Dr. Callaghan said that the boy had suffered from periodic attacks of vomiting and diarrhœa and some abdominal pain for several years, he had had periodic attacks of epistaxis, but no other haemorrhage. He was small, thin, and very pale, and his symptoms and general condition were obviously due to his spleen, which was so large that he had difficulty in walking. At the operation

very marked adhesions had been found between the spleen, the omentum, and the pancreas. The blood picture was consistent with a diagnosis of splenic anaemia. Dr. Callaghan thought that if the spleen had not been removed in this case the patient would not have lived. The blood count since the operation showed a very marked improvement. The Wassermann reaction was negative. About a fortnight after the operation the boy developed stiffness in the neck, and enlargement of the cervical glands was found. The pathological appearances conformed with those usually found in splenic anaemia, which was generally considered to be the pre-cirrhotic stage of Banti's disease; removal of the spleen was said to prevent the further development of this condition.

Mr. C. J. MACAULEY, who had performed the operation, said that splenectomy could be very easy or very difficult; in this case it was difficult because the boy's general condition was so poor, and he could not afford to lose much blood. Mr. MacAuley had employed a completely transverse incision, which allowed for the relaxation of the abdominal muscles, and so made the intra-abdominal proceedings more easy. Adhesions were numerous, and the separation of the tail of the pancreas was very difficult. Another advantage of a transverse incision was that it was quickly sewn up. Mr. MacAuley had thought of performing autotransfusion, but the blood squeezed out of the spleen was so full of debris that he was afraid to do so.

The PRESIDENT said that the question as to whether operation was the proper routine treatment for such cases could not be considered in this instance, as obviously the only thing to do if the child's life was to be saved was to remove the spleen.

The Significance of Achlorhydria.

Professor HENRY MOORE read a paper on the association of achlorhydria with certain pathological conditions. Of 745 patients submitted to fractional test-meal analysis, 168 (22.5 per cent.) showed achlorhydria. Of 21 cases of Graves's disease, 16 (76 per cent.) showed achlorhydria, and 19 (90 per cent.) a marked reduction or absence of gastric hydrochloric acid. Of 38 cases of diabetes mellitus 16 (42 per cent.) were found to have achlorhydria, and 22 (58 per cent.) showed marked reduction or absence of the gastric hydrochloric acid. Twenty-three cases of a moderate or severe low colour index anaemia with achlorhydria were described, and the possible rôle of the achlorhydria as a predisposing cause of the anaemia was discussed; the association of achlorhydria with a low colour index anaemia and its significance did not appear to have been recognized as a definite syndrome in medical literature. The treatment of this condition was described; it had been found that in five cases studied from this point of view the achlorhydria was still present after the blood picture had been restored to normal. Achlorhydria was found in 60 cases of diseases or complaints referable to the gastro-intestinal tract, and in 32 cases of miscellaneous conditions (excluding pernicious anaemia and malignant neoplasms). Five cases of hypocalcaemia with achlorhydria were also reported; in all of them the level of the blood calcium had been restored to normal by treatment.

The PRESIDENT expressed the belief that a great deal could be done to help research work in Dublin if practitioners who were not themselves working at a special subject would refer their cases to a specialist in that line. There was very little interchange between the hospitals, and it would greatly advance the knowledge in the Dublin school if members of the staff of various hospitals would pass on any cases which they could not thoroughly investigate themselves to another hospital where they could be studied by the appropriate specialist. Dr. G. E. NESBITT hoped Dr. Moore would draw some conclusions from his work in spite of the difficulty caused by the occurrence of achlorhydria in such very diverse conditions. He agreed that there should be more co-operation between the various hospitals, and that cases might be collected in groups and sent to specialists for investigation. Dr. HAYDEN remarked that the absence of hydrochloric acid in the stomach did not prove anything; until there had been further research on intestinal conditions, it would be very difficult to assess the true value of this acid in the body.

Reviews.

THE AUTONOMIC SYSTEM.

IN his recently published work on *The Autonomic Nervous System*,[1] Professor ALBERT KUNTZ has furnished us with a book of reference which will be widely appreciated. It will be particularly valued by British readers, because so much of the scientific basis of our knowledge of the autonomic system is based on the wide and philosophic researches of Gaskell and on the minute and painstaking investigations of Langley. The views on the subject now held in Great Britain and in America are unquestionably those that lead the opinions of the world, and Professor Kuntz gives us a well-digested and reasonably complete account of these views. To have collected so much information from such widely scattered sources and to have preserved proper historical balance must have been a considerable task, and it has been well done indeed.

The book opens with a description of the general anatomical relationships of the system and of its central connexions, and here it is interesting to note the close parallel between functions of the autonomic centres in the neighbourhood of the hypothalamus and the functions of the neighbouring pituitary body. Then follows a brief account of the physiology of the system and of its development, after which the autonomic supply of the various important systems is described seriatim. Of these chapters one of the most interesting is that on the autonomic innervation of skeletal muscle, since it involves the much-debated question of the relation of muscle tonus to special sympathetic innervation, on which the author has himself done a good deal of useful work. While he rejects the view that plastic tonus is subserved by the sympathetic system, he holds that removal of the sympathetic supply does diminish the resistance of extensor muscles to passive extension, and the whole of this difficult question is skilfully and fairly reviewed. The researches on the influence of sympathetic stimulation in delaying the onset of fatigue from motor excitation are also fully discussed, and though the author's own researches do not lend definite support to the view, he is inclined, it seems, to suspend judgement on the question.

After discussing the pathology of the autonomic system and the subject of referred pain, Professor Kuntz passes on to a discussion of the popular views on vagotonia and sympathicotonia. It would indeed be difficult for anyone, in a book dealing mainly with facts, to discuss at length so nebulous an aspect of the subject, and yet to do so with both enthusiasm and clarity; and this chapter therefore, though laudably brief, contains but little that is calculated to cheer the enthusiastic upholder of this greatly abused notion. Finally, there are chapters on the disorders and on the surgery of the autonomic nervous system. It is somewhat surprising to learn from the last how many operations have been performed on the autonomic system. Enthusiasts appear to have sympathectomized their hapless fellows for any and every reason, or for no reason at all. When one considers the serious reasons which the British laboratory experimenter must produce before applying to the Home Office for a certificate enabling him to remove the stellate ganglion from a cat, it is curious to note such exuberance of the experimental spirit in surgeons, and some thoughtful observers may wonder to what extent, in these sentimental days, the timidity of the one may have necessitated the boldness of the other, or even to what extent operative intrepidity and sound knowledge vary inversely.

The book is well produced and the bibliography is good, though it would have been better perhaps if the references had all been assembled alphabetically instead of being allocated to chapters of the book. There are some lacunæ, though not many. For instance, there is little reference to the sympathetic supply of the liver, though the liver is mentioned in connexion with referred pain. The index is certainly not so complete as might be expected with contents that represent such a mine of valuable information.

[1] *The Autonomic Nervous System.* By Albert Kuntz, Ph.D., M.D. London: Baillière, Tindall and Cox. 1929. (6×9½, pp. xii + 560; 75 figures. 31s. 6d. net.)

POST-OPERATIVE TREATMENT.

MR. P. LOCKHART-MUMMERY'S *After-treatment of Operations*,[2] now in its fifth edition, has earned a high place in the surgical literature of this country. It has, as its author claims in his preface, had a share in securing the emancipation of abdominal after-treatment from the starvation and prolonged recumbency that led in the past to so many complications and initiated so much chronic invalidism. The author's teachings are free from fetiches, and most of them he supports by excellent reasons. He includes very little that today would be regarded as controversial, and anyone criticizing the work on the grounds that his own or the pet fads are omitted may well ask himself if his own or the author's judgement is at fault. Mr. W. B. Gabriel contributes an interesting chapter on blood transfusion, in which he describes fully the citrate method, the Kimpton tube method, the multiple syringe method, and a two-way syringe method (*British Medical Journal*, March 24th, 1928, p. 492). Very brief reference is made to the use of gum saline in the treatment of shock, the only material which in Mr. Lockhart-Mummery's view is permanently effective being blood from another patient. During the diet after operations, he denounces the use of beef tea and meat extracts, and quotes from a recent writer on Napoleon the bloodshed caused by the warlike ambition of persons who have is as nothing compared to the myriad of persons who have sunk into their graves from a misplaced confidence in the food value of beef tea. Instead of beef tea he recommends egg albumen and rai-in tea, but omits reference to orange and other fruit juices which have a useful place in the post-operative dietary. White of egg mixed with orange juice is often very acceptable. The excellent chapter on abdominal after-treatment would be more complete if it included an account of the postural treatment for acute dilatation of the stomach. In advising a rest in bed of three to four weeks after hemorrhoids the author errs, perhaps, on the side of caution if he would apply this recommendation to the young adult patient in whom a treatment removal of the sac has sufficed; but there can be no doubt that such a period of confinement to bed would be necessary after a complicated hernioplasty in the middle-aged subject. Mr. Lockhart-Mummery's book is practical and clearly written. It deserves a place in the library of every young surgeon. Our only serious criticism is that it is worthy of a better index.

ARTHRITIS AND RHEUMATOID CONDITIONS.

MANY books have been written on the subject of arthritis in recent years, but the confusion of thought which is traditional to the subject has not notably diminished. One reason for this is the difficulty of classification. Dr. PEMBERTON has written a work on *Arthritis and Rheumatoid Conditions*[3] containing a great deal of general information as well as a detailed account of a number of original research undertaken by himself and his fellow-workers, both in the United States Army Medical Department and in the Presbyterian Hospital in Philadelphia, but it is doubtful if it will do anything to clarify the subject. He admits that classification is difficult, and tries to simplify the issue by adopting a simple grouping into atrophic and hypertrophic forms. So far so good but he immediately finds it necessary to qualify these simple terms and to differentiate the groups further into atrophic—proliferative—and hypertrophic—degenerative types. To the expert this nomenclature—though paradoxical will appear as essentially correct, but to the student it is bound to be very confusing. Dr. Pemberton, for all his attempts to achieve a simple classification, shows no inclination to over-simplify a complex subject, and as he proceeds he expounds the complex nature of the pathology, symptomatology, and treatment of the arthritides. He admits the importance of infection in the etiology of arthritis, but quite properly assigns to it an adjuvant rather than an exclusively causative role. He gives a long description of bacteriological experiments, mostly tending to negative conclusions, and assigns great importance to the observation that sugar is only slowly used by the tissues. This is in accordance with his own observation that large part of the capillary system are closed in arthritis. Such closure he regards as an allergic phenomenon, and points out that the same forms of treatment which are successful in the one case are capable of causing disturbance in the other. One very valuable lesson that may be learnt from this book is the danger to which even severe cases of arthritis can be subjected by unsystematic and careless treatment, and the author lays down a fine line of anti-treatment and the correct line of treatment, which are largely physical in nature, which are available.

The book is to be commended [illegible] errors [illegible] indeed [illegible] impression [illegible] to the early [illegible] fresh [illegible] our conception [illegible]

SOME PRESCRIPTIONS.

WE have received a copy of the tenth edition of *Pharmaceutical Formulas*,[5] which is described as a selection from various pharmacopoeias and other sources.

"You know my father left me some prescriptions
Of rare and proved effects, such as his reading
And manifest experience had collected
For general sovereignty."

The volume contains 1,146 pages. The index occupies 130 pages, and gives about 18,000 references, the bulk of which are to separate and distinct formulae. At first it is rather overwhelming to find that human ingenuity has devised 18,000 different modes of administering medicine to the sick. An examination of the contents diminishes the wonder, for much of this variety is a matter of permutations and combinations. Thus the eighty preparations listed as remedies for headache are for the most part merely changes rung on five common drugs. It must be confessed that most of the book makes heavy reading, though it is lightened here and there by interesting relics of the past. Confectio Damocratis, a mixture invented by Mithridates 2,000 years ago, is set forth in all the glory of its forty-four constituents. Reading this list makes one realize that medicine in modern times has lost a certain poetic touch. The names of modern synthetic compounds do not sound as pleasing to the ear as storax, bdellium, celtic nard, sagapenum, and spikenard, while there is something grimly mysterious about the last ingredient—bellies of scincs. At the end of the book seven pages are devoted to the history of the Medicine Stamp Acts, with a description of their provisions; and a dictionary of the difficulties arising out of these Acts occupies twenty-five pages. This dictionary shows what the legal mind can do when it works at high pressure. For example, all disorders of the skin—blotches, cutaneous eruptions, chilblains, and pimples—are ailments within the meaning of the Act, but blemishes of the skin—chapped hands, redness of the skin, and sunburn —are outside its scope. Again, dipsomania is an ailment, but inebriety is not, and a like distinction is drawn between obesity on the one hand and stoutness and fat on the other, while corpulence occupies a doubtful position. Neither a liver mixture nor an aperient mixture need be dutiable, but an aperient liver mixture is dutiable. Most readers will have heard of the absurdities and vagaries of these enactments, but when marshalled in dictionary form they are truly impressive. The volume is intended, of course, for the use of pharmacists, but the items we have picked out are enough to show that it contains much information of general interest.

NOTES ON BOOKS.

IN a small volume of less than ninety pages Mr. W. STUART-LOW presents his views on *Nasal Catarrh*,[6] which he attributes mainly to nasal obstruction. He describes the operations devised by him which he practises for the relief of this condition, and he also has much of a general nature to say about it. Except that there is no reference to treatment to say about it. Except the present book does not seem to differ much from his previous writings on the subject. The operations are probably not generally performed by the exact technique which he describes, but the methods he advocates are based on the sound principle of conserving the nasal mucous membrane as far as possible intact. The book is written in a popular style, and it is not quite clear for what class of reader it is primarily intended. The general public, the general practitioner, and the specialist are all provided with some food for thought, and, as Mr. Stuart-Low directs his attack upon one of the commonest of ailments, it would seem that he addresses himself to a wide circle of interested parties.

Dr. F. M. POTTENGER'S *Symptoms of Visceral Disease*,[7] the three previous editions of which in 1919, 1922, and 1925 were reviewed in these columns, has been revised and a new chapter added on the pharmacological and clinical tests for sympatheticotonia and parasympatheticotonia, but the size remains much the same, though the price has gone up by 15s. 6d. In the section on the viscerogenic reflexes of the lungs the author has considerably elaborated his conclusions, and hopes in the future to do the same for the other important organs.

The Cancer Research Committee of the University of Sydney has issued a record of *Investigations, Mainly on the Physiological Actions of X-Radiations*.[8] The director, Dr. H. G. Chapman, writes the foreword, besides contributing studies to the book. Radiotherapy has evidently been the subject of minute inquiry by these workers. The general opinion of the contributors is that, although the results of this method of treating cancer are as yet uncertain, its future is promising. Dr. B. S. Bishop, with some help from colleagues, has prepared a series of articles on the occurrence of lead in the egg of the domestic hen. Other papers record cytological observations on sarcoma in different animals.

The eighth volume of the *Nelson Loose-Leaf Living Surgery*[9] has been published as an *Index*. An index is not merely a catalogue of names and subjects, but an orderly procession of clues. It should therefore be designed to guide the reader. The publishers of the *Index Companion Volume* have kept this purpose in mind. Items are subdivided in alphabetical order, and each subdivision has a separate line. A subject can therefore be referred to at a glance. Related diseases are repeated under all related conditions. This convenient arrangement shows how two or more diseases may coexist, how one may predispose to another, and how they may be differentiated. Methods of treatment and how they are indexed separately as well as under the conditions for which they are employed. Indications and contraindications for surgery are given. Characteristic symptoms are also separately indexed. The volume is exceedingly well printed. It will be apparent from this brief notice that the publishers have not confined their energy and resource to the careful preparation of their articles only, and that the index is also evidence of an unusually enterprising spirit.

A pamphlet by Sir RONALD ROSS and Sir MALCOLM WATSON, entitled *A Summary of Facts Regarding Malaria Suitable for Public Instruction*, has now been published in a second edition by John Murray, at the price of 6d. The first edition appeared twenty years ago, and was reprinted five times. Brief particulars about the malarial parasite, mosquitos, and personal and public prophylaxis are here set out in plain language.

[5] *Pharmaceutical Formulas*, P.F. Vol. I. Tenth edition, entirely revised and rewritten by S. W. Woolley and G. P. Forrester. London: *The Chemist and Druggist*. 1929. (5¼ × 8¼, pp. vii + 1146. 15s.)

[6] *Nasal Catarrh*. By W. Stuart-Low, F.R.C.S.Eng. London: H. K. Lewis and Co., Ltd. 1930. (Cr. 8vo, pp. x + 84; 13 figures. 5s. net.)

[7] *Symptoms of Visceral Disease: A Study of the Vegetative Nervous System in its Relationship to Clinical Medicine*. By Francis Marion Pottenger, M.D., LL.D., F.A.C.P. Fourth edition. London: H. Kimpton. 1930. (Med. 8vo, pp. 426; 67 figures, 10 plates. 31s. 6d. net.)

[8] *Investigations, Mainly on the Physiological Actions of X-Rays and Allied Phenomena*. Conducted for the Cancer Research Committee of the Faculty of Medicine, Sydney; The University. 1930. (7¼ × 9¼; illustrated.)

PREPARATIONS AND APPLIANCES.

OPTOCHIN BASE.

OPTOCHIN BASE (Howards and Sons, Ltd., Ilford) is a preparation intended for the treatment of pneumonia. Professor Morgenroth and his co-workers prepared optochin (ethyl hydrocupreine), which is a synthetic derivative of quinine, and showed that the compound possessed a most remarkable specific action in killing the pneumococcus. The water-soluble salt, optochin hydrochloride, has been used successfully for local application in the treatment of pneumococcic conjunctivitis. Various attempts have been made to use optochin in the treatment of pneumonia, and American workers have recently claimed success with oral administration of the base. The method is to give five-hourly doses of the drug with milk for three days while withholding other food; it is claimed that by this method of administration enough of the drug is absorbed to confer pneumococcocidal properties on the blood serum. If the clinical results claimed are confirmed, then this method of treatment will constitute an important therapeutic advance. The difficulty of establishing with certainty the therapeutic value of a remedy for pneumonia is, however, well known.

NORMACOL.

Normacol (improved flavour) is a new preparation of the vegetable laxative prepared by Messrs. Napp, Ltd. No alteration has been made in the constituents, upon which the pharmacological action of normacol depends, but the flavour of the preparation has been improved.

THE GENIUS OF WILLIAM BOWMAN.

BEING THE BOWMAN LECTURE TO THE OPHTHALMOLOGICAL SOCIETY ON APRIL 3RD, 1930.

BY

SIR ARTHUR KEITH, M.D., F.R.S.

LET me, by way of introduction, refer to an incident from the life of Sir William Bowman which brings us at once *into close* touch with his personality. In 1863 the fiery but warm-hearted surgical dictator of the time, James Syme, Regius Professor of Clinical Surgery in the University of Edinburgh, and father-in-law of Joseph Lister, had publicly condemned the *operation* of iridectomy proposed by *von Graefe* for the relief of glaucoma in 1857. In 1863 Bowman was 47 years of age, and although he was Syme's junior by 17 years he was the acknowledged leader among the ophthalmic surgeons of England. He had already a wide experience of iridectomy, and, although he could not explain the rationale of the operation, he found it the only "certain and *indispensable*" treatment for acute glaucoma. Had Bowman been a "natural" man he would have rushed into print and trounced Syme in public for misleading the profession, but being master of himself and knowing that truth could be vindicated in a better way *he wrote* Syme a very direct personal note. The merits of iridectomy, he told him, were based on "facts which were numerous and positive"; the "rules for its application were precise"; "its results were capable of being anticipated with as much certainty as can be done in any department of our uncertain art." Syme replied that his condemnation of iridectomy was founded "on serious consideration of the anatomical, physiological, and pathological conditions in question," and that he foresaw unlimited dangers to the eyes of patients were the profession in general to practise the operation. To this Bowman replied that he had no wish to influence opinion except by sound reason." The answer from Edinburgh was brief. "*Iridectomy*," wrote Syme, "whatever may be its value for cure of blindness, will never interfere with the respect and regard which I entertain for yourself," and promptly dispatched the correspondence for publication in the *British Medical Journal*,[1] where his condemnatory statement had first appeared. I quote from this brief correspondence not only because it reveals the character of those two eminent Victorians in a favourable light, but also because it permits me at the outset of my address to illustrate the exceptional personality of the man who was invited to be president of this society when it was founded just fifty years ago.

SIR WILLIAM BOWMAN.

What was the secret of the high regard in which Sir William Bowman was held by his contemporaries? In his youth, as we shall see, he made brilliant discoveries in anatomy; these were known to only a few. In the full tide of his professional life he did more than any man in England to advance ophthalmology, a branch of medicine into which he was swept by force of circumstance. Such services are better known to you than to me, and I do not propose to consider them, but they *do not account for* the esteem in which he was held by his professional colleagues in all departments of medicine. It was not my privilege *to know him*; he died in 1892,* the year in which I became a unit in the medical life of London. I have to regard him, as have most of you, with the cold eye of posterity, but I am certain that those who knew him would never ascribe his ascendancy to the iridescence which shines in life and dies with a man. The *personality which captured* the heart of James Syme must have been moulded out of permanent and sterling stuff.

You must permit me to pursue my inquiry into the personality of Bowman because of a change in my outlook on medical history. If you had done me the honour ten years ago of inviting me to give this lecture in his memory I would have started by directing your attention to his discoveries, recounted them one by one, measured their worth, and sought for the circumstances which guided him from point to point in his career. Having done that I would have dismissed in a sentence or two all those qualities and activities of mind and heart which we call *personality or character, in the belief* that personality has no place in the narration of those events which make up the history of medicine. But now I would alter the order *of my treatment and place* personality first.

BOWMAN'S CHARACTER.

Bowman lived in a period in which *medical knowledge* was advancing with great rapidity; he was a Victorian; he entered King's College in 1837 at the age of 21, and before he was 25 he had "advanced" medicine by a series of notable discoveries. He was endowed with certain excessively rare gifts of mind without which no advance or discovery is possible. In King's College *he found himself in an atmosphere of research. But* rare gifts of mind, skilful hands, encouraging surroundings, do not explain the career of William Bowman. What urged him on? He must have cherished some ambition which had to be satisfied, or formulated some ideal which had to be attained. In his personality there must have been, as in all who seek to *improve the state of mankind*, some missionary quality which drove him onwards. When we look beneath the surface of medical history—and Sir William Bowman's life is part of it—we see that the mainspring of all our progress lies not *in man's intellectual equipment*, but in those qualities which we, *in our ignorance*, attribute to his heart. The urgent desire for betterment lies not in man's head but in his heart.

On a few occasions only did William Bowman give his contemporaries a glimpse of the motives which regulated his life. The first of these is somewhat disappointing: it is a paper read to his fellow medical students at King's College *in 1838*, his second year. One is more impressed by the rotundity and balance of his sentences than by the rather trite ideas which he expounded. At one point, however, he shows us where his heart lies; it is with the poor. He counsels his fellow students to show respect for *the dead* by the "purity and neatness of our dissection." We come across the same leading motive in the first lecture he gave to the students at Moorfields Hospital in his thirtieth year, having been appointed assistant surgeon to that institution in 1840. After referring to the

* Bowman died on March 29th, 1892, aged 76, at his country house on the Surrey hills between Guildford and Dorking, and was buried in the neighbouring churchyard of Holmbury St. Mary.

Clearly it is impossible in the course of a single lecture to recount all the discoveries which distinguished William Bowman's earlier years of toil in King's College; but I must refer, very briefly, to his work on the organs of sense. When you compare the account which Dr. Arthur Jacob, professor of anatomy and physiology in the Royal College of Surgeons in Ireland, wrote on the eye for the *Cyclopaedia* (vol. ii, 1839) with that which Bowman prepared for Todd's *Physiological Anatomy* you feel as if a century, not a year, had elapsed between the times of their preparation. Jacob's account of the eye was that obtainable by dissection with needles aided by a hand lens; Bowman's account is our modern one, the eye as revealed by sections observed through a compound microscope. As we read Bowman's descriptions we marvel, not at the revelations of the microscope, but at the sureness of his interpretation. Our conception of the cornea remains much as he left it; the ciliary muscle had no certain existence until he defined its relations, nature, and function. It is true he supposed that it served accommodation by altering the position not the form of the lens. He detected the circular and radial musculature of the iris; it was left for Koelliker and particularly for young Joseph Lister, working under the inspiration of Wharton Jones a decade later (1851), to amend his conception of the structural elements of that musculature. He saw the optic fibres circle on each side of the "yellow spot," yet dismissed the "spot" as of little importance in vision because it was not present in the eye of the dog, cat, rabbit, and bird, animals with perfect sight. He refused to regard the rods and cones (bulbs) as concerned in perception because they lay on the outer or "wrong" side of the retina. With a flash of insight he speaks of the eye as "a sheet of nervous matter brought towards the surface of the body to meet the appropriate stimulus"; in another passage he states that the relationship between the retina and the "sensorium" is a problem "too inscrutable for our limited powers." Nevertheless I think it may be said with truth that Bowman made a larger contribution to our knowledge of the anatomy of the eye than any other investigator.

The additions he made to our knowledge of the finer structures of the inner ear are at once apparent when we compare his account with that contributed by Wharton Jones to the second volume of the *Cyclopaedia* (1839). I first became aware of the importance of Bowman's observations on the ear about twenty years ago, when preparing an account of the structure of the cochlea for a work published by the late Sir Thomas Wrightson. We owe our present conception of the basilar membrane to William Bowman; it was he who first described its elastic and striate zones, its denticulate lamina and outer spiral ligament.

I must not give the impression that Bowman saw everything that was to be seen within the field of his microscope; he even made mistakes, but there are surprisingly few of them. For example, he had proved that the ciliary "ligament" of the eye was in reality a muscle, and served in the accommodation of vision. He applied the same conception to the ear, and believed that the outer spiral ligament of the basilar membrane was muscular in nature, and served in the accommodation of hearing. He missed the organ of Corti (it was first described in 1851), and thought that the tubular fibres of the auditory nerve ended directly in the basilar membrane. He was unable to follow nerve fibres to their true terminations. The technique needed to fix the delicate epithelial parts of sense organs and to define the final ramification of nerve fibres was unknown in his earlier years; hence we find that he went astray in regard to the sensory structures concerned in sight, hearing, smell, taste, and touch. He was certain that capillaries did not perforate the sarcolemma of muscular fibres, and concluded that it was the same with their nerve fibres.

It is even more interesting to observe, in connexion with the "cell doctrine" enunciated by Schwann in 1839, that there still clung to him something of the old metaphysical Adam. For example, he believed that new epithelial cells of mucous membranes arose not from other cells, but from granular intercellular substance. He also mentioned that bone cells (osteoblasts) could and did arise from the granular medullary matter. On the other hand, he admits that "in the early development of the embryo all the tissues, however dissimilar from each other, consist at first of nucleated cells." When, however, we make allowance for the primitive methods then at the disposal of microscopists, and the novelty and vastness of the field in which he laboured, it is surprising, not that he was sometimes in error, but that he was so often right.

I now come to what seems to me to be the enigma of William Bowman's life. In those earlier years, from his twenty-second until his twenty-sixth year, investigation followed investigation and discovery succeeded discovery. Then his ardour for research seems to have suddenly cooled. It is quite true that in 1846 he investigated the appearances seen by the microscope in experimental wounds of the cornea—a pioneer piece of research of the highest importance; there was also a study of the vitreous body, but thereafter he was concerned with wards rather than with laboratories. It is also true that at the height of his professional career he seldom allowed a year to pass without making an important addition to the resources of ophthalmic medicine and surgery. Nevertheless, the results of the last fifty years of his professional life (1842–92) did not fulfil the brilliant promise of those earlier years. What had happened? In 1842 he married most happily. Did his home tempt him from his laboratory? Or was it that research did not provide him with that fullness of life which his intellectual and artistic nature craved for? Or was it that, in spite of his great scientific accomplishment, he found that his way into the field of general surgery was blocked, and that, against his inclination, he was compelled to take a side path in his chosen profession?

BOWMAN AND LISTER: A PARALLEL.

One cannot help speculating how surgery would have developed in England if, at the end of his earlier years of arduous research, William Bowman had become surgeon to King's College Hospital in the place of Sir William Fergusson. Would he have prepared the way for Lister and made the path of antiseptic surgery easier? No one, so far as I know, has drawn attention to the many striking resemblances between these two men. Bowman was born in 1816, Lister in 1827. Both had educated well-to-do English parents; both had fathers who had a strong bent for scientific inquiry; Lister, like Bowman, was a natural draughtsman; both chose the more scientific schools for their medical education—the one King's College, the other University College. Both came under leaders in the new movement in anatomy—Bowman under Todd, Lister under Sharpey and Wharton Jones. Both became masters of the microscope while still students. Bowman's first research was into the structure of muscle; Lister's first research was to correct Bowman's description of the musculature of the iris. Both proved in their first publications that they were not apprentices but master workmen. Both became Fellows of the Royal Society. Physically they had also much in common; their tastes were similar. Both were moved by the same deep-rooted desire to relieve suffering, to help the poor and the unfortunate; both sought to improve surgery by inquiry and experiment in the laboratory; both sought to base their art on science. Both suppressed self to an extreme degree; both sought earnestly after truth; they were equally modest, humble, and unassuming. Both possessed in their clarity of thought, in their precision of statement, and in the finality of their proof, the same qualities as Harvey. Both were laboratory men; Lister was so all his life. Would Bowman have still resorted to his laboratory if he had become professor of surgery in King's College while his enthusiasm was still ablaze?* One cannot resist these speculations. They are perhaps futile and vain, but of this we may be certain, that if general surgery suffered a great loss in the direction which Fate gave to Bowman's career, ophthalmic surgery reaped an exceedingly great reward.

CORONARY OCCLUSION.

THE development during the early years of the twentieth century of precise instrumental methods for the diagnosis of heart disease was greeted at the outset with some scepticism. Our profession has a way of approaching new wonders first with mistrust, then with enthusiasm, and later with renewed scepticism. In this case the third phase, that of philosophic doubt, was provoked by failure of the instrumental methods to fulfil the over-sanguine expectations that were aroused during the middle period. The pendulum of opinion has swung to and fro, thesis has given place to antithesis, and the conflict between enthusiasm and scepticism has resolved itself in a reasoned view that recognizes both the potentialities and the limitations of instrumental methods. These methods, it is realized, yield data which, assessed together with evidence arrived at by other means, may contribute to an accurate diagnosis; they cannot in themselves, except very rarely, furnish a diagnosis. When during the early years of the century James Mackenzie showed how precision in the diagnosis of arrhythmias could be obtained by means of the polygraph, and Thomas Lewis followed with his studies in electro-cardiography, it seemed as though the problems of cardiological diagnosis had been solved. A period of reaction followed, when clinicians began to wonder whether they had not been too hopeful, for the results yielded by the new methods, though academically interesting, seemed to guide them but little in arriving at a diagnosis or deciding on a course of treatment. But the pact between the traditional clinical methods and those demanding the use of instruments of precision has been profitable in many directions, one of the most noteworthy being in the diagnosis of coronary occlusion. In most cases this condition may be identified from its clinical features alone; but an electro-cardiogram, though not always distinctive, sometimes provides the only absolute evidence of its existence. In his brilliant monograph entitled *Coronary Thrombosis: Its Various Clinical Features*,[1] Dr. Samuel A. Levine, of the Medical Clinic of the Peter Bent Brigham Hospital, Boston, Massachusetts, notes the curious fact that in England coronary thrombosis failed to secure recognition as a clinical entity for many years after it had been fully accepted in the United States. Thus it is thirty-three years since Dock reported one of the earliest cases of coronary thrombosis diagnosed during life and confirmed at necropsy. Fourteen years elapsed before there appeared the next noteworthy clinical study of this subject, by Obratzow and Straschesko. Since then a slowly gathering stream of publications has appeared, principally in America. Osler, Mackenzie, and Allbutt knew coronary thrombosis well as a post-mortem finding; but none of these indicated in his writings that the clinical features might suffice to differentiate it from angina pectoris. Indeed, in this country it was not until 1925 that the clinical distinction between these conditions began to attract attention, though since then it has gained widespread recognition.

An attack of coronary thrombosis may, according to the localization of the pain, resemble closely one of two conditions: angina, or an acute abdominal emergency. The distinction from angina is not always easy. Coronary occlusion, however, is not precipitated by effort, and frequently it occurs at night. The pain is agonizing, persistent, and paroxysmal, now and then subsiding for a short time, only to be renewed with greater intensity; usually it is retro-sternal, but its distribution may correspond with that of a typical angina. In some cases the pain is localized to the abdomen, and, being accompanied by a varying degree of muscular rigidity, is apt to be mistaken for gall-stone colic, or attributed to the perforation of a gastric ulcer. During an attack the blood pressure falls considerably, and the pulse becomes weak, and often irregular; whereas in angina the blood pressure tends to rise, and the pulse rate to remain unchanged. Far from being held "bent rigid and immobile" in the classical attitude of angina, the patient restlessly turns this way and that, tearing at his breast in the extremity of his pain. A most important point in the differential diagnosis is that the pain responds to no drug except morphine. Amyl nitrite brings no relief whatever; it may in fact do harm by lowering the blood pressure still further. In a proportion of cases clinical examination reveals a small area of pericardial friction, due to the formation of an infarct. When this sign occurs after an attack characterized by the above symptoms it is pathognomonic; but its absence is of little significance, for it seldom lasts more than a few hours and often the site of infarction is inaccessible to the stethoscope. In the occasional atypical case which is painless throughout, an electro-cardiogram may afford the only conclusive evidence of the presence of coronary thrombosis. There is therefore every reason, especially as an electro-cardiograph can so easily be brought to the bedside, for invoking its aid in the diagnosis of any difficult case.

More of theoretical than of practical importance is the question of localization of the infarcted area. Barnes and Whitten[2] found that left coronary obstruction was followed by inversion of the T wave in lead I or leads I and II; if, on the other hand, those parts of the heart supplied by the right coronary artery became infarcted, T-wave inversion occurred in leads II and III. Obviously, if the formation of a mural thrombus is followed by its detachment and embolism, the accompanying symptoms and signs may indicate whether this has originated from the right or the left side of the heart. Such evidence is not an infallible guide, however, since left coronary obstruction may give rise to mural thrombi in both ventricles, through involvement of the interventricular septum. It seems probable that electro-cardiographic findings must ultimately be of greatest importance in the localization of cardiac infarctions.

Elsewhere in this issue (p. 631) will be found an excellent account by Dr. Crighton Bramwell of the clinical course of coronary occlusion, illustrated by several case records. Both Bramwell and Levine, it may be noted, draw attention to a characteristic constitutional type associated with coronary occlusion. According to Levine, the typical patient is a well-set person, somewhat over-weight, often of considerable physical strength, who enjoyed unusually good health. That there is a hereditary factor in their production is brought out by Drs. Hexamith and [illegible] in their record (p. 685) of a series of cases showing a familial

[2] Barnes, A. R., and Whitten, M. B. Amer. Heart J., October, 1929, i. 14.

liability to sudden death in relatively young men with sclerotic coronary arteries; Levine, too, noted that many of the patients had a family history indicating a susceptibility of the vascular system to degenerative disease. Syphilis seems to be associated but rarely; indeed, Levine, who found it in only 4.5 per cent. of cases, doubts whether syphilis has any direct causative influence in the production of coronary thrombosis. Rheumatic infections are associated even less frequently: "In fact," states Levine, "it may be said that not only do patients suffering from coronary disease have no history of rheumatic fever, but that those having rheumatic heart disease but rarely show coronary disease. This probably is true even of those younger rheumatic patients having aortic insufficiency who may have attacks of angina pectoris." Diabetes, on the other hand, appears to have an important bearing on the development of coronary thrombosis. Its presence does not alter the prognosis or influence the age at which attacks occur, but the two conditions are so commonly associated that it seems as though diabetes, even if it has no direct etiological significance, indicates a type of patient with a vulnerable vascular system. The statistical relation between coronary thrombosis and diabetes is difficult to assess, for among the many cases that have been held to illustrate such a relation it is probable that there were some in which the glycosuria was transient, and due to the great pain and fear that go with an attack of coronary thrombosis.

Coronary thrombosis has a grave prognosis, but it is difficult to predict the outcome of any individual case. A patient having apparently a mild attack may die suddenly; in a most desperate case the symptoms may clear up. Moreover, an attack successfully combated is inevitably followed by others, and there is no way of knowing how long the fatal attack will be delayed. Treatment may be summed up in eight words: absolute rest, morphine in large doses, and hope. Rest is essential, because the site of infarction may be covered by a mural thrombus, which is liable to become detached in the early stages. Stimulation of the heart is allowable at the onset of the attack and for the following day or two, but is contraindicated thereafter until the end of the second week unless the inception of abnormal rhythm or the occurrence of cardiac failure renders such treatment imperative. Nitrites, as we have said, may be actually harmful.

AMPUTATIONS AND ARTIFICIAL LIMBS.

For many years amputations were the most commonly performed major operations even of civil surgery; in military surgery they had a still more prominent place as a rough-and-ready treatment of limbs severely damaged on the field of battle. A good idea of the proportion of the wounded in naval warfare who suffered this drastic but necessary procedure is brought out in a letter written by Midshipman Samuel Thornton to his father on April 12th, 1814, describing the famous naval duel between the American frigate *Essex* and her English counterpart, the *Phoebe*. According to Thornton, whose letter was quoted in the *Times* of March 8th last, 44 primary amputations were performed on the captured ship; and as the wounded on the highest estimate numbered no more than 70—the casualty lists of the action are inaccurate—this would imply that over 60 per cent. of them suffered amputation.

During the century between 1814 and 1914 improvements in surgery made amputation increasingly rare in hospital practice; indeed, in 1913, according to Mr. Edred Corner, only 34 of the 5,843 operations performed at St. Thomas's Hospital were amputations. Early in the campaign of 1914, however, the prevalence of gas gangrene and other septic conditions, and the large number of compound fractures and gross lacerations of soft parts, brought these operations once more to the front, and revived the interest of surgeons in artificial limbs. Furthermore, since the war the number of accidents due to motor traffic on the roads "has increased, is increasing, and ought to be diminished"; and though no statistics on this point are available it is certain that the number of amputations in civil life must be several times as great as it was in the years immediately preceding the war. The assembling of many hundreds of cases at Roehampton in 1915 gave members of the surgical staffs of Queen Mary's Convalescent Auxiliary Hospitals an opportunity of studying this subject, and enabled them to suggest tentatively certain modifications of previous practice. In the following winter, in a small pamphlet that was widely circulated among the surgical staffs of military hospitals, they set forth the sites and kinds of amputations which up to date had been found to give the best results from the point of view of the limb-fitter. This pamphlet, but little altered, was reissued towards the end of the war.

That a great deal of the officially recommended war-time practice survives to-day was brought out at the discussion on amputations and their relation to the artificial limb held on April 2nd at the Section of Surgery of the Royal Society of Medicine. From the report which appears in this issue (p. 693) it will be seen, however, that the present tendency is to decry long thigh stumps and Syme's amputation, the late results of which have been learned from experience accumulated since the war years. When Muirhead Little's book[1] was published in 1922 the excellence of the round stump operation in which the femur was divided some 3 inches above the articular surface was hardly questioned, and it was generally held that the advantage through the extra leverage obtained by saving on the average 15 inches of femur outweighed any risk of malnutrition. To-day this operation is discredited, and those who practised and advocated it realized that their hopes and beliefs of ten years ago were illusory. Similarly discredited is Syme's operation, which, properly performed in suitable cases, was held to produce one of the best stumps known. The experience of a dozen years has led many surgeons to discard it, on the ground that it is followed by late-appearing troubles, such as callosities of the scar and tenderness. In a large proportion of the war cases this operation had been rendered necessary by frostbite gangrene, the permanent ill effects of which often extended far higher than the site of amputation. In such circumstances it followed that the resulting stump had poor vitality and was abnormally sensitive; from the first patients had trouble with the prosthesis, and the need for re-amputation was common. It may be questioned, therefore, if it is safe to generalize about amputations on the basis of experience gained among war pensioners; whether, indeed, different conclusions might not be arrived at from a study of civilian cases in which there has been no complicating sepsis extending beyond the site of amputation. We do not know if statistics bearing on this subject are available, and it may be difficult to collect them, but the results of the suggested comparison could not fail to be of interest. We cordially agree with the speakers about the comparative worthlessness of such procedures as the amputations of

[1] *Artificial Limbs and Amputation Stumps.* London: H. K. Lewis & Co., Ltd., 1922.

Pirogoff, Gritti, or Stokes-Gritti, and, indeed, of all osteoplastic amputations. Nature is a better bone grafter than the most skilful surgeon; given a fair chance, she shuts off the medullary cavity of a long bone with precision, though in some circumstances she may produce exuberant bone in the form of spurs. But it is remarkable how seldom spurs of the bone cause disability and inconvenience in stumps. Prostheses in the upper extremity have small practical value, except in special cases. The unfortunate individual who has lost both hands may be obliged to rely upon artificial substitutes, though it is astonishing how much may be done with two bare long forearm stumps. In very many cases the man with one sound arm and hand, especially if it is the right limb that is intact, will wear a prosthesis only as an ornament or to conceal mutilation. Here, more than in the lower limb, the necessary harness is irksome and hinders the free use of the sound limb.

The importance of fitting sockets to stumps cannot be exaggerated. A bad fitting means loss of power of control and injury from friction and uneven pressure. The ideal fitting, in which the stump and the socket move as if they were all one piece without any play between them, gives comfort to the wearer and minimizes the sensation of weight and strain. Lightness, a well-designed mechanism, and good material are all obviously important in limb prosthesis, but good fitting is the most important of all. The best limb badly fitted may from the wearer's point of view be inferior to a much cruder appliance with a well-fitting socket.

PREPARATIONS OF ERGOT FOR ORAL ADMINISTRATION.

DURING the past year the properties of ergot preparations have been studied systematically at the Pharmacological Laboratory of the Pharmaceutical Society. Messrs. Wokes and Elphick[1] studied the alkaloidal content of various samples of ergot and found that the Polish ergot contained 0.6 per cent., whereas the average Spanish or Portuguese ergot contained about 0.2 per cent. Mr. Wokes[2] studied the stability of ergot preparations and obtained disappointing results; he found that liquid extract of ergot, made according to the directions of the *United States Pharmacopœia*, when freshly prepared, contained a considerable quantity (0.1 per cent.) of the specific alkaloids, upon which the therapeutic action of ergot depends. Unfortunately the preparation proved to be unstable, for even when stored in an ice chest, it lost half its activity in ten weeks and in twenty weeks less than a quarter of its original activity was retained. Concentrated soft extracts of ergot were found to be rather more stable, but these also lost half their activity in from four to nine months. The conclusion from these results is that better methods of preparation need to be discovered before reliance can be placed on ergot preparations. Dr. J. H. Burn[3] investigated the absorption of ergot from the alimentary canal of cats, and found that when defatted powdered ergot was given by mouth to cats about 30 per cent. of the alkaloid was absorbed, and that the drug maintained its action on the tissues for at least two days. The tragic history of epidemic ergotism proves clearly that ergot in the solid state can maintain its activity for long periods. These experiments in conjunction with the results of Wokes suggest that the best preparation of ergot for administration by the mouth is probably the defatted powdered drug.

COMPULSORY NOTIFICATION OF ACUTE RHEUMATISM.

THE rheumatism scheme of the Royal Borough of Kensington having been in operation since October, 1927, Dr. James Fenton, medical officer of health, and Dr. R. C. Lightwood, physician in charge of the rheumatism supervisory centre, are able, in their second annual report just issued, to take stock of progress, and provisionally to assess the value of the system of compulsory notification which was instituted in the first place for an experimental period of three years. They are satisfied that the establishment of the rheumatism supervisory centre has been amply justified, and believe that it is a preventive agent that should be placed on a permanent basis throughout the country. But their views about the value of compulsory notification are still so indefinite that they suggest the desirability of continuing the system of compulsory notification beyond the original experimental period in order that they may accumulate more facts to guide them. Before the expiry of any period of renewal they believe that they will be able to arrive at a final opinion in favour either of increasing the scope of the regulations to include some as yet unnotifiable forms and manifestations of rheumatism, or of rescinding the regulations altogether. At present they are of opinion that compulsory notification would be of greater value if the expression "acute rheumatism" were amended in the Kensington regulations to cover rheumatic pains or arthritis, or rheumatism chorea, or rheumatic heart disease, occurring separately or together in a child under the age of 16. The diminution in the notifications during the second year—105, as against 159 in the first year—was to some extent expected, because there was an accumulation of cases which immediately became due for notification on October 1st, 1927, when the scheme was first put into operation: it is probably true also that during the second year there was some tendency on the part of practitioners to overlook notification. Of the 105 patients whose cases were notified, 77 attended the centre, but 37 of these were notified by the medical officers of the centre itself. The experience of the neighbouring borough of Hammersmith, which, without any provision for the notification of rheumatism, is yet able, through the efforts of the Invalid Children's Aid Association, to refer an increasing number of children to the Kensington centre, suggests that a rheumatic supervisory centre backed by an energetic voluntary organization, can do a great deal of useful work without any scheme of compulsory notification. On the other hand, Drs. Fenton and Lightwood point out that though notification provides the centre with but a small proportion of its cases, it brings to their notice patients of whose existence they would otherwise be ignorant. Moreover, notification is useful in ascertaining those rheumatic children who, after recovering from an acute attack, are not kept under their doctors' supervision. Outside the sphere of the supervision and treatment of rheumatic children notification has been valuable in facilitating environmental research, and it would, the authors of the report believe, be advantageous to continue in existence three or four municipal schemes of notification in the London area in order that such environmental investigations might be allowed to mature. As an alternative to notification they suggest that the school medical service might be able to deal effectively with the control of rheumatism, though perhaps not with its present organization. Rheumatism supervisory centres could be fed chiefly by the school medical service, and other bodies encouraged to refer children to the centres, even children below school age. Drs. Fenton and Lightwood recommend that in each area rheumatism centres should be set up in close association with the existing hospitals, and staffed by physicians of general experience.

EUROPEAN WOMEN IN THE TROPICS.

THE effect of life in the Tropics upon European women was the subject of a short discussion in the Section of Tropical Diseases of the Royal Society of Medicine on April 3rd. Dr. G. W. Theobald, speaking as one who had practised gynaecology in the Tropics, said that the tropical environment, whether mental or physical, was bad for men but worse for women. Men proceeding to the Tropics had to submit to medical examination, but the majority of women went as wives, and were not necessarily medically examined, or if an examination was made it was not by a gynaecologist. No statistics appeared to be available as to the number of women who became infected with malaria; the Colonial Office and the India Office had no figures. Dr. Howard Cook, secretary to the medical committee of the Church Missionary Society, had stated that during the last ten years no woman missionary of the society had died from malaria, and only seven out of a total of *eight hundred in the field had been invalided* home with that disease. All the missionaries of the society were advised to take quinine daily. The majority of residents in the Tropics, said Dr. Theobald, would continue to live in real danger of malaria until the Governments concerned realized that effective malaria control was a necessary and economic policy. One requisite of life in the East was a more or less mosquito-proof dress, which could be made very attractive for women, but, as matters stood, many women spent several of the hours after sunset (when the anopheles began to bite) in evening frocks which exposed a large surface of the body to attack. He considered it was time that malaria experts expressed their disapproval of sleeping nets which tucked in under the mattress, for the foot, elbow, or hand might rest against the net, and so present something for the mosquito to bite. Screened houses were built by Americans, but avoided by British; nevertheless, he thought they lowered the incidence not only of malaria but of other fly-borne diseases. The round of social engagements and vigorous sports, which occupied many women's lives in the East as an escape from ennui, was not conducive to resistance. It was often said that women could not stand the climate, when the fact was that even under British climatic conditions such a programme as they attempted in India could not be undertaken without harm. In sharp distinction were the missionary women, who did not take alcohol or attend many social functions; they very often lived in the most uncongenial surroundings, without the luxuries of fans and ice, but they worked harder than they had done at home, and they remained remarkably fit for a great number of years. Dr. Theobald gathered that the balance of opinion was against women taking quinine as a prophylactic; there was no clear proof, however, that small doses affected menstruation, conception, or pregnancy. Even if there was a certain small amount of risk of terminating the pregnancy, it was necessary in the interests of the mother, the child, and the race that malaria should be energetically combated. As an obstetrician he had used quinine to induce labour in a number of cases, all of them thought to be almost at term, and out of 52 of which he had records it had failed to have this result in six. In all but one of these 52 cases the children were born alive. He believed that quinine increased the length and the severity of the normal uterine contractions, but it did not induce labour until the patient was at or very close to term. There was no need, however, for heroic doses as a malarial prophylactic; 10 grains in the morning and 10 grains at night were sufficient for the average woman, and such doses would not affect the course of pregnancy. In the course of the discussion the president of the Section (Dr. J. B. Christopherson) suggested that if women in the East would wear trousers it would be a great step towards malaria prevention. A mission in Africa had devised for its women members a dress proof against *Glossina morsitans* and included that garment. Sir Andrew Balfour said that it would be some advantage if women would wear two pairs of stockings instead of one, for the mosquito would not bite through more than one thickness. He mentioned also that it was now the custom in India to have bright lights fixed under the table at dinner; in such luminosity the mosquito would not bite. The screening of the verandah was very useful, and the description "stuffiness" applied to the screened house was not necessarily true. The conditions of the Tropics affected the nervous system of Europeans deleteriously, of women more than men, partly because women were more highly strung and partly also because they often had not sufficient employment, and so tended to overdo sport and social functions. Dr. Manson-Bahr considered that certain types of women were less suited than others to tropical life: the blonde type, preferred by mosquitos, was much more liable to break down than the brunette. He also expressed the view that in the majority of instances where abortion occurred under quinine, the abortion was due not to the quinine but to the malaria. Dr. G. C. Low said that, examining for a large missionary society working in Central Africa, he had refused to pass any woman who had any menstrual disturbance, and that since the examination had been made more strict the incidence of illness in the mission field had fallen considerably.

BENEVENUTUS GRASSUS.

REPRINTS of the classics are always interesting. The medical profession in general, and ophthalmologists in particular, owe a debt of gratitude to Dr. Casey Wood of Stanford University, California, for his translation of the *De Oculis, eorumque egritudinibus et curis* of Benevenutus Grassus of Jerusalem.[1] This little book is a true incunabulum, for it was printed before the year 1500 A.D.; the exact date may not be quite settled, but Dr. Casey Wood advances cogent reasons for placing it in 1474. The only other early printed book dealing with the eye would appear to be the *De Oculo Moradi* of Archbishop John de Peckham, printed by Anton Sorg at Augsburg in or about 1475. Dr. Casey Wood says of this latter work that "the contents are in the main a series of priestly homilies and quotations from the Fathers in which a rather good description of the visual apparatus, together with its diseases and their treatment, serves as a peg on which to hang saintly saws and religious dogmas." Considering his period, Peckham was a profound mathematician with a knowledge of optics second only to that of Roger Bacon, but he was not a medical man, and knew no practical ophthalmology. Grassus's work, on the other hand, is intensely practical. His treatment of trachoma—everting the lid, scarifying the conjunctiva, and expressing the contents of the granules—would pass muster to-day. He is cautious in the use of the cautery as a counter-irritant to the head and temples; he gives excellent advice as to the removal of a pterygium; and in his ocular treatment he never fails to call attention to the importance of considering the general health, as was fitting in one who had lectured at Salerno. His topical applications sound for the most part bland and unirritating; he is altruistic enough to admonish his hearers to treat the poor without fee; but if, for instance, powdered pearls or sapphires are indicated in the treatment, and the patient is wealthy, there is no reason why these should not be prescribed. It is a treat to find a mediaeval textbook which refrains from recommending dung, dead men's bones, coffin rings, and other nastiness as therapeutic measures; the urine of a

[1] Benevenutus Grassus of Jerusalem: *De Oculis, eorumque egritudinibus et curis*. Translated with notes and illustrations from the first printed edition, Ferrara, 1474 A.D., by Casey A. Wood, M.D., LL.D. Calif.: Stanford University Press; London: Milford, Oxford University Press. 1929. 23s. net.)

haste youth is the nearest thing we get here to such applications; while the apple poultice so often recommended was probably very efficacious, and we should not be surprised to hear of such treatment having been used by the more illiterate of the inhabitants of remote country districts within living memory. When couching for cataract the operator, having dislocated the cataract, is advised to hold it down long enough to repeat four paternosters. Not the least interesting part of the volume is the scholarly introduction by the translator. The late Professor Hirschberg was of the opinion that Grassus was a renegade Jew. Dr. Wood thinks that this book "does not necessarily picture an apostate Jew adding enough Christian savour to leaven the heretical text of his unbelieving book, but rather the act of a prudent printer-publisher, who, safeguarding his own interests and following the custom of the country, had brought the work 'up to date' by introducing, here and there, a few churchly maxims." This small volume was for more than 500 years the most popular ophthalmic manual of the Middle Ages. There are twenty-two manuscripts of the text extant, and about eighteen printed editions. Of the Ferrara (1474) edition, here printed, only eight copies are known to exist: three are in America, the Pierpont Morgan copy having been purchased in 1905 from an English sale; one copy is in the library of the Royal College of Surgeons of England; and the other four are on the Continent—two in Paris, one each in Naples and Rome. The book is enriched by fine illustrations of the first and last pages of the Ferrara edition, with one of the pages from the middle of the book (No. 33). There are also illustrations of a Provençal MS. of the thirteenth century, and the *explicit* and last folio of the old English Ashmolean codex in the Bodleian Library. The publishers deserve great credit for the beautiful paper, printing, and format of the book.

THE TOBACCO PROBLEM.

THE March issue of the *Bulletin of Hygiene* contains a review of recent literature on the tobacco problem by Dr. J. D. Rolleston, who has collected figures from various countries illustrating the enormous and increasing consumption of tobacco, particularly in the form of cigarettes. In Germany, for example, it has been calculated that the average number of cigars consumed yearly by males over 14 is 300, and of cigarettes consumed by adults of both sexes about 700. In the United States the figures for 1928 were 102,764,698,000 cigarettes, 8,036,714,162 cigars, and 378,874,261 pounds of tobacco in other forms. A good deal of attention has recently been given to the nicotine content of cigars and cigarettes, and most investigators appear to be agreed that the term "denicotinized" applied to various tobacco products and particularly to cigarettes is a misnomer. Though as a group the so-called denicotinized products contain less nicotine than tobacco not specially treated, some contain as much nicotine as is found in ordinary tobaccos, while none is sufficiently low in nicotine to warrant its unrestricted use by persons liable to suffer ill effects from the alkaloid. Dr. Rolleston remarks that though the relation of tobacco to public health has received rather stepmotherly treatment in this country, it has aroused more interest in Germany and the United States, where some hygienists not only hold that tobacco is in no way an aid to health, but recommend that smokers should undergo a thorough physical examination periodically in order to detect any ill effects that tobacco may have produced on the circulation. Lickint, in an interesting paper, of which Dr. Rolleston gives a full summary, analyses the tobacco consumption in a series of 100 men over 80 years of age. In this series there were 10 men over 100 years of age, and among these 3 had never smoked, 4 were still smokers, and 3 had been smokers, but were no longer so. The remaining 90, aged between 80 and 100, included 19 who had never smoked, 32 life-long smokers, and 39 who had given up the habit. It is noteworthy that all the smokers consumed tobacco either in pipes or in the form of cigars; none of them was a cigarette smoker, probably because when cigarettes were introduced into Germany these men were already too old to change their habits. Lickint suggests that the growing popularity of cigarette smoking, being accompanied by an increase in the practice of inhaling, whereby tobacco produces its most injurious effect, is leading to a diminution in the expectation of life. In another investigation among younger men Lickint had found that the proportion of non-smokers ranged from 5 to 8 per cent. The fact that among old men the proportion was much larger he believes is due to a passing of the taste and tolerance for tobacco with increasing years.

NATIONAL UNION OF STUDENTS.

THE National Union of Students, which is at present appealing for an establishment fund of £30,000, is the only organization that unites the students of universities and university colleges of this country in a single body. Its wider purpose is to eliminate national prejudice by facilitating more regular intercourse among students in all parts of the world. Internationally, it fosters a better understanding between the students of the Empire and those of other countries, partly through the Confédération Internationale des Etudiants, comprising thirty-eight national units, and partly by the interchange of groups of visiting students. It is non-sectarian and non-political. During the seven years of its existence "faculty" tours have been arranged in medicine and in fifteen other subjects. These tours are designed to give medical students first-hand experience of the practice of their profession abroad, and to provide them with widespread opportunities for studying the psychology and problems of the countries they visit.

BRITISH POST-GRADUATE HOSPITAL AND MEDICAL SCHOOL.

THE Minister of Health made an important announcement in the House of Commons on April 9th in regard to the founding of a British Post-Graduate Hospital and Medical School in London. He said that the Post-Graduate Medical Education Committee, appointed in 1925 by his predecessor, Mr. Chamberlain, had presented its report, and that the Government, after full consideration, had accepted the scheme put forward by this committee. In order to secure without delay the advantages of a proper system of post-graduate education in London, the committee proposed that a hospital and school should be organized comprising: (1) the existing public hospital at Hammersmith with 400 beds in modern wards, which on April 1st became the property of the London County Council, and will continue to be maintained by the rates; (2) a medical school, connected with the hospital, which will have to be built and maintained; and (3) a residential hostel, to be established in Central London. To ensure realization of this scheme the Government has decided to contribute from public funds a capital sum of £250,000 for building and equipping the school, in addition to providing for annual grants towards its maintenance through the University of London. In regard to the proposed hostel, the Government understands that an appeal with which it is in full sympathy will shortly be made to the public for funds to establish a residential institution, to be called "London House" for the use of students from the Dominions and Colonies, not only in medicine, but in other arts and sciences. Further reference to Mr. Greenwood's statement and to the Post-Graduate Medical Education Committee's report will be made in our next issue.

THE OPHTHALMOLOGICAL SOCIETY.

JUBILEE CONGRESS.

THE annual congress of the Ophthalmological Society of the United Kingdom, which took place in London, under the presidency of Mr. LESLIE PATON, F.R.C.S., from April 3rd to 5th, coincided with the fiftieth anniversary of the society's foundation, and the occasion was marked by the visit of an unusually large number of foreign ophthalmologists. Among those who offered congratulatory addresses at the opening of the congress were Professor Van der Hoeve (Leyden), Dr. M. Marquez (Madrid), Professor Josef Meller (Vienna), Professor F. Terrier (Paris), Dr. Henri Coppez (Brussels), Professor Emile de Grosz (Budapest), Professor F. C. Ask (Lund), and Professor Giuseppi Ovio (Padua). In the course of five sessions more than twenty papers were read, and the Barnes Hall of the Royal Society of Medicine was filled on each occasion.

A preliminary ceremony was the presentation of the Nettleship medal to Miss Ida Mann for her contributions to ophthalmology, particularly in its embryological aspect. One interesting event of the congress was a visit to the Zoological Gardens, where Miss Mann demonstrated the reptilian iris under the slit-lamp. Among the reptiles taken as examples were the gecko, the lizard (whose eyes were much the most beautiful), the python, and the frog. She pointed out that the arrangement of the vessels in the reptilian iris was fairly definite according to species, but pigmentation seemed to be absolutely fortuitous, and she could not say how this was determined.

On the first evening of the congress a reception was given at the Royal College of Surgeons. The visitors were received by Lord Moynihan, the President, and Mr. C. H. Fagge and Mr. Warren Low, Vice-Presidents. In addition to the more usual exhibits at Lincoln's Inn Fields a special display had been arranged by the curators in the shape of old ophthalmic instruments, microscopes, and books. On the following day Sir Arthur Keith delivered the Bowman Lecture, taking as his subject the genius of Bowman. This is published at page 701 of our present issue.

Presidential Address: Control of Position and Movements of the Eyes.

Mr. LESLIE PATON devoted his address from the chair to a consideration of the reflex factors controlling the position and movement of the eyes. He said that in man and other animals with frontally placed eyes and binocular vision the retinal stimuli played a predominant part in such control, but in lower types, with laterally placed eyes, other factors came into prominence, the most important of these being reflex stimuli originating from the labyrinth and from the neck muscles. These factors were also present in man, but were not so easily made manifest, though when their proper function was interfered with, signs and symptoms resulted which were often of grave significance and usually difficult to interpret. Among the most important of these signs and symptoms were vertigo, nystagmus, and nausea or vomiting. These lower controls were best studied in the rabbit or guinea-pig, in which it was found that every position of the head in space, and of the head relative to the trunk, produced its corresponding position of the eyes. There was a direct control by the labyrinthine stimuli and by proprioceptive impulses from the neck muscles on the eye positions. It was evident that the stimuli emanating from the sacculus and utriculus depended on gravitational pressure and might be called gravistatic. The stimuli from the neck muscles varied with every condition of contraction and relaxation, and might be called tonic; the stimuli from the semicircular canals initiated movements in the eyes, and were themselves initiated by variations in the fluid pressure in the canals acting on the gelatinous capsules covering the cristae ampullae, so that the activity of the semicircular canals might be described as kinetic. Anatomically the paths concerned in all these controls of eye movements and body equilibrium were very complex, and impulses might travel to their final common path by more than one route. Some of these paths were known, but many were yet obscure. Until they were more fully worked out it would not be possible to solve the problem of nystagmus nor many of the other problems involved in the interpretation of some of the more difficult forms of ocular palsies and disturbances.

Endocrine Disorders Associated with Eye Diseases.

The principal discussion of the congress was on disorders of secretion of the endocrine glands associated with eye diseases. It was opened by Mr. J. H. FISHER, who said that it was now fairly well established that the interrelation between the functions of the endocrine glands was provided by the chief hormones which each supplied and which were carried in the blood stream to all parts of the body. In some degree the product of one ductless gland might serve as a fair substitute for that of another. The hormones of some were antagonistic to, or corrective of, those of other glands, and an excess of one might stimulate the production of another; the balance must be held most carefully between the whole group if normal growth, health, and vitality were to be maintained. The endocrine glands were factories, each turning out its special product, which was sent into the blood stream. Possibly investigators had gone astray in concentrating so much attention on the "factory" and overlooking the importance of the material. Was the enlarged thyroid or pituitary the preliminary derangement, or might not the gland have been disorganized for want of raw material? Biochemists would do well to renew their investigations of the constitution of the blood from which the ductless glands drew their raw material, and into which they poured their products.

Professor H. MACLEAN remarked that little was known with certainty about the endocrine glands; he commented also on the ignorance about carbohydrate metabolism, for work done during the past two or three months went to show that views firmly held up to a year or two ago were all wrong. It had to be admitted now that practically nothing was known about the various reactions which took place in such a condition as diabetes. He thought, however, that in typical progressive diabetes the fundamental difficulty was in the tissues, which were unable for some reason to utilize or burn up sugar. If the liver lost its power to store the incoming sugar as glycogen, the blood in the peripheral circulation would be flooded with sugar, and there would be hyperglycaemia. The real defect concerned in the glycosuria of the elderly was not any difficulty in oxidizing or burning sugar, but in storing sugar in the liver. This condition was sometimes associated with some slight acetonuria, but the speaker did not believe that this primary difficulty in liver storage was really dependent on a pancreatic lesion at all. There was a certain amount of evidence completed recently that the pancreas was not the only organ which took part in this metabolism; the liver also acted, and it was in glycosuria associated with difficulty in liver storage that the retinal effects were noticeable. This condition went on year after year. In typical diabetes, on the other hand, there were not so many eye lesions seen, especially nowadays, because the condition in its usual form was very striking, and was quickly recognized as requiring insulin. He also suggested that the retinal changes seen in Bright's disease were due to high blood pressure and had nothing to do with the kidney.

Professor E. C. DODDS expressed some doubt regarding the ophthalmological textbook description of exophthalmos as due to the action of thyroid secretion in the blood. It was impossible to correlate the basal metabolic rate determination with the amount of exophthalmos. Exophthalmos might be unilateral, and might advance or recede quite irrespective of the general condition. As to retinitis occurring in diabetes, Professor Dodd's observations confirmed the view that this condition occurred only with associated arterial degeneration. All the diabetics admitted to the institution with which he was connected had had their retinas examined, and it had always been possible to correlate retinal changes with arterial degeneration. He had practically never found change in the retina associated with early diabetes. In conclusion, Professor Dodds said that biochemists were expected to provide solutions for these and other difficult problems, but he did not think they were given a fair opportunity. How many post-ophthalmic hospitals had a biochemist on their staff?

Biochemists at the general hospitals could give information on the negative or control side—they could say that a certain condition of the blood precluded a certain condition of the eyes—but for the other side of the story it was necessary to seek the experience of a biochemist engaged closely with ophthalmic cases.

Dr. W. CLARK SOUTER showed some interesting charts and pictures of clinical cases, and Mr. A. W. ORMOND and Dr. C. GOULDEN contributed to the discussion.

Papers and Demonstrations.

The many papers presented to the congress can only be briefly indicated. Mr. E. TREACHER COLLINS discoursed on the effect of deficiency in vitamin A in bringing about eye changes. He showed how, in such deficiency, the mucus-secreting cells of the conjunctiva atrophied and ceased to function so that keratinization of the epithelium took place. In the absence of mucous secretion the surface tension of the conjunctiva altered, and the fatty secretion of the meibomian glands adhered to it, forming an excellent pabulum for the growth of micro-organisms, pathogenic and non-pathogenic, the former exciting an inflammatory reaction, which in the cornea resulted in keratomalacia.

Dr. W. R. AYKROYD, from experience of Newfoundland and Labrador fishermen, spoke on the frequent association of functional night-blindness with external eye condition, unquestionably due to vitamin deficiency, suggesting that the former had the same etiology. Cod-liver oil or fresh liver would usually quickly cure this "nutritional dyskotopia," the term suggested for this particular form of night-blindness.

A very comprehensive paper was read by Dr. JAMES COLLIER on the various patterns of ocular paralysis resulting from infective or toxic processes, such as diphtheria, polyneuritis, botulism, and veronal intoxication, and of ocular paralysis growing in myasthenia gravis, for which there was as yet no pathology. Dr. Collier had been fortunate enough to observe quite a large number of unusual and illuminating cases, which he mentioned. He indicated four varieties of patterns of paralysis as met with clinically: the peripheral paralysis, in terms of the distribution of the peripheral oculomotor nerve or one of its branches; the supranuclear paralysis, in terms of the physiological use of the eyes, upward and downward movements, lateral movements, and convergence; the nuclear paralysis characterized by its irregularity, by the affection of both eyes, by the constant loss of parallelism, and by the presence of nystagmus; and, finally, the paralysis resulting from the specific selective activity of a poison upon a particular physiological mechanism—for example, the isolated paralysis of the ciliary muscle so common in diphtheria.

Dr. J. W. TUDOR THOMAS gave a remarkable demonstration in the form of a preliminary report on a series of experiments, carried out in the physiology department of the Welsh National School of Medicine, on the transplantation of the cornea in rabbits. The importance of finding a successful method of corneal grafting was that it opened up the possibility of restoring some sight to many at present incurably blind. Dr. Thomas described the main types of operation carried out. In his experience the cross-stitching operation gave by far the best results, and this was the only method by which he had obtained clear grafts. This was a central round graft with shelving edges, held in place by stitches inserted in the cornea, the stitches being arranged with the limbs crossed. Out of 14 experiments, 13 of the grafts united, and of these, 4 grafts were clear, and the four rabbits with clear corneal grafts were demonstrated at the meeting. The demonstration evoked a great deal of interest, and was the subject of some appreciative remarks by Sir Arthur Keith at the banquet the same evening.

Mr. W. S. DUKE-ELDER outlined some experimental work demonstrating the effect of choline and acetyl-choline on the extrinsic muscles of the eye. The matter arose during research upon the effect of various drugs on the intra-ocular circulation, when peculiar reactions upon the intra-ocular pressure were registered with choline. These were traced to a contraction of the recti and obliqui muscles, which was unaffected by atropine and abolished by nicotine and curare.

Some cases of damage to Descemet's endothelium were described in a paper by Mr. FRANK JULER. The first case was that of a man in whose anterior chamber a spicule of glass had been present for twelve months before detection. In three cases the cornea became opaque after irrigation of the anterior chamber during extraction of cataract; two were imbibition opacities, and the third was probably due to a deposit of calomel in the lining of the chamber. Another group was the condition of Fuchs's epithelial dystrophy of the cornea. Mr. Juler described two cases occurring in sisters, which is unusual.

Mr. F. B. CHAVASSE entered on an examination of the existing theories of concomitant convergent strabismus. He criticized strongly the accommodation theory, which, he declared, failed on various grounds. Taking all the theories of squint, including the theory that it was due to ocular inequality, there was not one that covered all the cases. Professor VAN DER HOEVE produced a striking collection of illustrations of malformation of the eye, as well as of other facial deformities, the result of amnion bands. Dr. GORDON HOLMES discussed the spasm of fixation; Mr. DOGGART read a paper on ocular rosacea, and Mr. GREEVES described x-ray applications in superficial keratitis. Mr. BERNARD CRIDLAND commented on the certified causes of blindness, and there were yet other papers for which time did not allow of adequate discussion.

The Congress Banquet.

The concluding social event of the congress was a banquet at Fishmongers' Hall, when 150 sat down at the tables under the presidency of Mr. LESLIE PATON. In proposing "The Health of the Society," Mr. Paton traced its history back to the little group of energetic men who used to meet in the house-surgeon's room at Moorfields to discuss ophthalmic questions. There were 114 original members of the society, of whom 11 were still alive, and two of them—Sir Thomas Barlow and Mr. J. B. Lawford—were present on that occasion. He mentioned the names of many outstanding figures in the early days of the society. At one time there was danger lest the society should lose its identity in the Royal Society of Medicine, but an arrangement was devised whereby it remained independent and pursued a distinctive line, though in the happiest relations with the large and flourishing Ophthalmic Section in that body.

Sir THOMAS BARLOW entered further upon reminiscence. The society began, he said, as a small club in the late seventies. It had been his happiness to work with Edward Nettleship, the mainspring of the society, and one of Hutchinson's most distinguished note-takers who had carried note-taking to a fine art; a quiet, reserved, dignified man, with a passion for accuracy, his own most severe critic, a conscientious clinical investigator, and a man of great intellectual and moral culture. Of other great names associated with the society he mentioned Jonathan Hutchinson as the "universal specialist," and Hughlings Jackson, whose discoveries regarding optic neuritis were the most fruitful and important in the whole of neurology. Jackson's philosophical reflections on the involved problems of neurology were an education in themselves. He brought to everything he touched a philosophical grasp. One of the great things that struck Sir Thomas Barlow about the society was that it made a common meeting ground for physicians, surgeons, and pathologists. For this reason the society was a lesson to the whole profession.

Sir JOHN PARSONS, in a witty speech proposed "The Health of the Bowman Lecturer," and Sir ARTHUR KEITH, in reply, praised the ophthalmological school on this country, which, he said, was one of the three strong schools of specialists in Great Britain, the others being the physiological and the neurological. Mr. J. H. FISHER proposed "The Health of the Guests," to which a charming response was made by Professor VAN DER HOEVE, who, in the name of the foreign visitors, presented to the society an ivory gavel suitably inscribed. Sir JOHN BLAND-SUTTON, who also responded for the guests, said that he attended a meeting of the then young Ophthalmological Society in December, 1880: he was invited thereto by George Critchett, an extremely dexterous surgeon, whom he saw perform his first operation of iritomy. In those days most of the ophthalmic work was done by general surgeons.

Sir John Bland-Sutton mentioned the extreme antiquity of ophthalmology, which was studied by the Greeks and Romans, who treated people for cataract: probably ophthalmology was older than surgery itself. It was curious how the phenomena of light and radiation had now come to dominate specialism. Since the invention of the incandescent lamp and the discovery of *x* rays five or six Sections had been added to the Royal Society of Medicine, all indicating specialisms which used light or radiant energy in some form or other. Every new instrument devised, of course, required dexterity in its practice to be successfully used, and thus specialism was encouraged. But he maintained that the ophthalmoscope was the prince of clinical instruments and ophthalmology the most justifiable of specialties

The gathering concluded after toasting "The Health of the President" and expressing thanks to the Prime Warden of the Fishmongers' Company, whose splendid hall gave a dignified setting to a memorable occasion.

LEAD TETRA-ETHYL IN MOTOR SPIRIT.

DEPARTMENTAL COMMITTEE'S FINAL REPORT.

THE final report of the Departmental Committee on Ethyl Petrol,[1] appointed by the Minister of Health on April 2nd, 1928, to inquire into the possible danger to health arising from the use of this type of motor spirit, reaffirms the conclusion of its interim report, summarized in the *British Medical Journal* of August 4th, 1928 (p. 219)—namely, that there are no reasons for prohibiting the use of ethyl petrol in this country so long as adequate precautions are observed. The committee, under the chairmanship of Sir Frederick Willis, held seven further meetings, and heard evidence from Professor H. E. Armstrong and Dr. Roche Lynch, senior analyst to the Home Office. Dr. Edgar's evidence, which was referred to in the interim report, was supplemented by Dr. Kehoe, who was also responsible for much of the scientific work undertaken in the United States by the Ethyl Gasoline Corporation. The results of the investigation—carried out under the supervision of the Public Health Department of the United States during the last few years—were examined by the committee in the preparation of its previous report; but further inquiry was considered desirable, particularly in regard to the effect of inhaling ethyl vapour when spilling occurred in garages. The general results of this inquiry, which consisted of a number of investigations conducted by the committee's experimental staff, were corroborated by evidence obtained in Canada and Australia.

Detection of Lead in Urine.

Experimental work in the United States had revealed that urine in normal conditions contained minute quantities of lead. As the committee was not satisfied that the method of detection employed in reaching this conclusion was sufficiently accurate, a new and more refined method was devised which could be used for testing other biological substances as well. No reason was found to disagree, however, with the results of the American experiments, which had also shown that comparatively larger quantities of lead were excreted by town-dwellers and by workers exposed to special risks. It appears from the report that the results of the chemical analysis were in harmony with the medical data of the persons (male) from whom the samples were taken. The average amount of lead found in all the samples of normal urine examined was 0.04 milligram per litre.

Settled Dust of Streets and Garages.

Evidence of lead contained in dust, which is stated to be a cause of its excretion in normal conditions, might be expected to disclose a basis for ascertaining the possible amount of air pollution when ethyl petrol is more extensively employed as motor fuel. This is considered doubtful, as the proportion of lead was found to vary as widely as *nil* to 3.3 per cent. in samples of dust collected in London and neighbouring country districts. The committee gives some indication that the risk of chronic plumbism, arising from the daily inhalation of dust or fumes over a long period, is remote, and observes that the proportion in the settled dust of factories using lead is much greater than in garages. The value of this experiment, however, so far as garages are concerned, is lessened by the fact that no sample of dust could be obtained from a garage using ethyl petrol exclusively.

Danger to Health from Spilling.

In commenting on the interim report we referred to the need for more precise information about the danger to health from residual evaporation when spilling occurred. It was obvious that possible risks depended, partly at least, on the quantities spilled, and on the size and ventilation of the building. A large quantity spilled in a small unventilated garage might be supposed to have an injurious effect, and this danger is not concealed in the report. The committee concludes, however, from its own observations and by reference to a series of American experiments, that the risk from short exposures to a maximum concentration of lead under severe conditions appears to be slight, especially as the spilling of large quantities happens, it presumes, only occasionally. With adequate ventilation the possible danger from the spilling of small quantities, even repeatedly, is regarded as negligible. Asphalt, concrete, and wood evidently reduce the amount of lead concentration in the air, which is also affected by the nature of the other elements in the mixture.

The Committee's Conclusions.

The committee's principal conclusions, briefly expressed, are as follows:

1. Urine, in normal conditions, contains a minute quantity of lead, the proportion being less in persons who live in the country. Excretion of lead is caused partly, if not mainly, by inhaling dust containing lead. On an average there is a fairly close relation between the degree of exposure to lead and the proportion of lead in the urine.
2. No evidence has been found to indicate that the settled dust in a garage where ethyl petrol was regularly used for some cars contains more lead than that of garages where this fuel is not employed.
3. Lubricating oil from the crank cases of cars using ethyl petrol contains a small proportion of volatile lead; the proportion of non-volatile lead associated with the insoluble "carbon" in the oil is significant. Deposits scraped from the cylinder heads, pistons, and exhaust systems of the engines contain a negligible quantity of volatile lead.
4. Oily deposits from the combustion chamber and exhaust pipes of cars run on ethyl petrol are unlikely to cause serious contamination of any water supply; deposits free from oil will have no serious effect on a water supply of a moderate degree of hardness, but the contamination of a soft water supply by oil-free deposits might be more serious.
5. Risks to health from spilling large quantities of ethyl petrol appear to be slight; if adequate ventilation exists the risk from the spilling of small quantities appears to be negligible. Garages should be efficiently ventilated and spilling should be avoided.
6. It is improbable that pedestrians would inhale a dangerous quantity of lead when "puffs" are blown out of the exhaust pipes of motor vehicles during the acceleration of their engines.
7. The risk from absorption of lead tetra-ethyl owing to contact of ethyl petrol with the skin is so small as to be negligible.

Recommendations.

The general impression conveyed by the committee is one of painstaking accuracy not only in assembling the results of its own experiments, but in the lucid presentation of the data collected from other sources. It is obviously premature to express an opinion on the validity of its conclusions until ethyl petrol is more extensively employed as a motor fuel in this country. Many of the results of the experiments are supported by data from the United States, but it is conceivable that even they may lose their authority in course of time. It is therefore desirable that tests of this nature should be resumed at regular intervals. Meanwhile the committee advises no legislative action so long as the precautions outlined in our previous summary are secured by the terms of the contract between proprietors and vendors. These are:

1. That cans and pumps should be labelled to indicate the presence of lead in the fuel and to warn the user to avoid spillage and not to use the fuel for purposes other than motor fuel.
2. That the fuel should be dyed as an additional check against its use otherwise than as motor fuel.
3. That the amount of lead tetra-ethyl in the fuel sold for ordinary commercial purposes should not exceed 1 part in 1,32 parts by volume, or about 1 in 650 by weight.

HENRY HILL HICKMAN CENTENARY.

RECEPTION AT WELLCOME HISTORICAL MUSEUM.

On April 2nd (exactly one hundred years after Henry Hill Hickman's death) a noteworthy gathering was held at the Wellcome Historical Medical Museum in Wigmore Street, London, to commemorate Hickman's researches in connexion with inhalation anaesthesia, and to hear an address on the subject by Lord Dawson of Penn. In form it was a reception by the authorities of the museum to the Section of Anaesthetics of the Royal Society of Medicine, but the company included many other representatives of medicine and surgery. Among the guests were Lord Moynihan of Leeds, President of the Royal College of Surgeons, Professor A. H. Burgess, President of the British Medical Association, Sir Farquhar Buzzard, Sir D'Arcy Power, Sir Francis Shipway, Sir Holburt Waring, Mr. V. Warren Low, and the president of the Section, Dr. R. E. Apperly. Two of Hickman's granddaughters, Mrs. Bettridge of Tenbury and Miss Blanche Thompson of Birmingham, also attended.

In the absence of Dr. Henry S. Wellcome in America, the guests were received by Dr. C. M. Wenyon, chief director of the Wellcome Bureau of Scientific Research. A special centenary exhibit had been arranged in the portrait gallery of the museum. This included the authentic records of Hickman's experiments and demonstrations, his portrait, another oil painting showing him experimenting with anaesthesia on animals, certain letters and memorials, and a number of personal relics, such as the scales and weights and mortar and pestle which he used in his practice, the door-plate from his surgery at Tenbury, and a notice card from his consulting room intimating that he was "at home every Tuesday from 10 o'clock until 4, for the purpose of giving advice gratis to the poor and labouring classes." It was explained that many years ago, when Dr. Wellcome was preparing his museum, he made special researches for evidence of agents employed at various periods to lull and numb the senses, and the history of anaesthesia thus explored brought to light certain documents relating to the part played by Hickman in that history. Further documents were obtained from official archives in Paris and from members of Hickman's family, and this material was added to the Wellcome Museum.

HENRY HILL HICKMAN, M.R.C.S.
(From an oil painting in the Wellcome Historical Medical Museum.)

We may recall here that the first allusion to Hickman's discoveries in recent times was made by Mr. C. J. S. Thompson in an article he contributed to the *British Medical Journal* of April 13th, 1912 (p. 843).

A Noteworthy Souvenir.

A handsome souvenir of the occasion, produced by the Wellcome Foundation, Ltd., was presented to the guests. This work, of 70 pages, is much more than a complimentary brochure, because it represents the first publication in full detail of the Hickman material which the museum possesses. In addition to the rather pathetic narrative of Hickman's life, it contains a large number of illustrations bearing on his work, and reproduces some fifteen pages of closely written MSS., most of it from the pen of Hickman himself. His own record of his experiments is included, his famous (but futile) appeal to Charles X of France in 1823, and extracts from the French records, as well as a later series of letters by Dr. Thomas Dudley of Kingswinford, in 1847, to Mrs. Hickman, then a widow, relating his unavailing efforts to secure posthumous recognition for this young pioneer. The famous pamphlet of Hickman, published in 1824, its title beginning *A Letter on Suspended Animation* . . . . is also published in full, together with appreciations by Dr. J. D. Comrie and Dr. Dudley Buxton.

Address by Lord Dawson.

Lord DAWSON, after pointing out that the commemoration owed its fruition to the enthusiasm and energy of Dr. Cecil Hughes and the public spirit of Dr. H. S. Wellcome, said that in order to estimate faithfully the work of Hickman it was necessary to picture the life of his time, and to take measure of the state of knowledge and thought belonging to his day. Far back in the beginnings of history there existed a desire and an effort to discover a means of relief from pain and suffering, and it was curious to note that only in the eighteenth century did there seem to arise a feeling that pain was an inevitable accompaniment of human life. That indifference to pain became extended to surgical practice, and the same apathy, extending into the nineteenth century, was probably responsible for a very noteworthy fact—namely, that between the discovery and application of anaesthesia no less than forty years elapsed. During that period those who should have been concerned were so blind that they did not apply the perfectly obvious inference that should have been drawn from the experiments of the great scientists at the end of the eighteenth century. Anaesthesia, as now known, owed its origin to the discoveries of Lavoisier, the great French philosopher, to the discovery of hydrogen by Cavendish in 1766, the discovery of nitrogen by Rutherford, and, lastly, the discovery of oxygen by Priestley. The discovery of nitrous oxide by Priestley about 1774 was followed in the year 1800 by the important discovery of its anaesthetic properties by Humphry Davy. Davy, having investigated the effects of nitrous oxide on animals, published his researches in an interesting book, in which occurred a pronouncement of which Lord Dawson asked his hearers to make a mental note: "As nitrous oxide in its extensive operation appears capable of destroying physical pain, it may probably be used with advantage during surgical operations in which no great effusion of blood takes place." Humphry Davy had discovered the idea but it fell on deaf ears, and in 1818, when Faraday announced that "when the vapour of ether mixed with common air is inhaled it produces effects very similar to those occasioned by nitrous oxide," the imagination of the medical world still remained untouched.

Lord Dawson then introduced his audience to Hickman, who began his career as a practitioner in Ludlow, Shropshire, and to whom had to be given credit for appreciating the sufferings inflicted by surgical operations and the conception of means to alleviate them by the production of insensibility. Hickman was, in fact, the first to put these ideas to the test of experiment. He rendered animals unconscious, first through partial asphyxiation by the exclusion of air, then by inhalation of carbon dioxide, and later of nitrous oxide. During anaesthesia Hickman made incisions, applied ligatures, amputated ears and limbs, all without pain and with good surgical results. His earnest purpose was to extend the benefit of his findings to

mankind, and accordingly he came to London and put his views before the surgeons of his day. They turned down all Hickman's notions as fantastic. His famous pamphlet, *A Letter on Suspended Animation . . .*, remained a witness, however, to his scientific spirit and method. Ultimately Hickman went to Paris and presented to Charles X a memorial praying that his work might be presented to the Académie Royale de Médecine. That body went a step further than Hickman's compatriots, for a commission of investigation was appointed, but the investigation was never carried out. Having failed to gain recognition in France, as in England, for the work to which he had sacrificed his career, Hickman returned to his home, where he died in 1830, when only 30 years of age.

Continuing the history, Lord Dawson said that from 1831 onwards there gradually grew up, particularly in America, but also in England, a fashion of inhaling ether and nitrous oxide to the point of excitement, and even semi-intoxication. This was done out of motives of fun and curiosity, and among medical students and other youths such inhalations became a pastime—a sort of early version of the cocktail party! From time to time those indulging in such frolics became anaesthetized, and yet the scales did not fall from the eyes of the surgeons. It was not until 1842 that a young dentist, Crawford Long, used ether for the first time for a definite surgical purpose—namely, the extraction of a tooth. Then events followed more quickly, for in 1844 Wells employed nitrous oxide for anaesthesia at operations, and Morton, unaware of Long's work, in 1846 administered ether in Massachusetts General Hospital—the first public anaesthesia. In 1847 the distinguished French physiologist Flourens applied chloroform for the first time to animals, the results being sufficiently satisfactory to lead Sir William Lawrence at St. Bartholomew's and Sir James Young Simpson in Edinburgh to apply chloroform to human beings. Simpson was the first to publish details of about fifty cases of successful administration for anaesthetic purposes. Lord Dawson put it to his audience that when they came to adjudicate on what must be called the fruition of anaesthesia they must, in fairness, decide that the greater part of the credit belonged to three early workers—Humphry Davy, Michael Faraday, Henry Hill Hickman.

It was interesting to inquire why so many years separated the discovery from the adoption of anaesthesia. Was it because Great Britain, at the end of the eighteenth century and the early part of the nineteenth, was passing through a phase of apathy, not only of mind but of feeling, which led to insensitiveness towards pain? There was evidence of the truth of that suggestion, for Sir John Thomson-Walker had been kind enough to lend him a manuscript book of a surgeon who lived in the early part of the nineteenth century, and practised in Norwich. The book contained the most minute and accurate descriptions of various operations, and although the surgeon did all without any anaesthetics, never once was there expressed any concern for the pain the patient might be suffering. There was, however, another reason besides apathy. Necessity for and even pride in rapid operating might have excluded other considerations from surgeons' minds. The great Liston prided himself on being able to amputate a leg at the hip-joint in less than a minute. Of course, it had to be remembered that constructive surgery as now known did not exist in those early days; surgery then consisted, in large measure, in removal of parts of the body. Hickman, though a young country practitioner, without any of the advantages of access to town and to learned bodies, had the mind to see and the heart to feel what anaesthesia meant for humanity, and strove his hardest to get his colleagues in the surgical world to apply the results of what he had proved by experiment. He failed, just as Humphry Davy and Faraday had failed; but now honour was Hickman's due, and it was the privilege and happiness of all concerned on that centenary occasion to perpetuate his fame.

The Hickman Memorial.

After a hearty vote of thanks had been accorded, on the motion of Dr. APERLY, to Lord Dawson for his address, Dr. MINNITT expressed appreciation on behalf of the Section of Anaesthetics and the committee of the Hickman Memorial Fund to Dr. Wellcome for his hospitality, to Mr. L. W. G. Malcolm, the curator of the museum, for his assistance in gathering the historical facts concerning Hickman's work and character, and to all who had helped the fund, by subscription and in other respects. Dr. CECIL HUGHES announced that the amount received in connexion with the fund totalled £256. After expenditure on the family graves and on the memorial tablet, the residue would go as an endowment to encourage original work of merit in connexion with anaesthetics, which would, it was hoped, perpetuate Hickman's name and assist the progress of the branch of science to which he devoted his life. The names of the trustees appointed would be published later in the medical journals, to the editors of which thanks were due for the publicity afforded.

It remains only to add that on April 5th a tablet was unveiled in Bromfield Parish Church, in the yard of which Hickman lies buried. The tablet bears the following inscription.

A . M . D . G

HENRY HILL HICKMAN

Member of the Royal College of Surgeons
Born at Lady Halton, in this Parish, Jany. 27
Baptized in this Church, January 30, 1800

Died at TENBURY, April 2
Buried in this Churchyard
April 5, 1830

This tablet is placed here at the initiative of the Section of Anaesthetics of the Royal Society of Medicine as a Centenary tribute to the memory of the earliest known pioneer of Anaesthesia by Inhalation.

HONOUR A PHYSICIAN WITH THE HONOUR DUE UNTO HIM

A.D. 1930.

The tablet was unveiled by Sir StClair Thomson and dedicated by the Bishop of Hereford. Among those present were Lord Plymouth, the vicar of Bromfield, and Prebendary Joyce; Mr. Warren Low and Dr. Cecil Hughes (treasurer and honorary secretary of the Hickman Memorial Fund), Dr. W. Watkins-Pitchford (representing the Council of the British Medical Association), the President and five past-presidents of the Section of Anaesthetics of the Royal Society of Medicine, and several descendants of Hickman.

NATIONAL RADIUM CENTRES.

STATEMENT BY THE RADIUM COMMISSION.

THE following official communication, briefly noted in our last issue at page 675, has been received for publication from the National Radium Commission. It is dated April 2nd, 1930.

The work of the Radium Commission has now reached a stage at which it seems advisable and convenient to make a further statement with regard to the progress of the national organization which it is engaged in setting up.

As already announced, the cardinal feature of this Commission's policy has been the concentration of national radium at a limited number of centres in England, Scotland, and Wales, where there are medical schools with complete clinical courses and where treatment of patients can be combined with the education in approved methods of radium therapy.

Twelve Centres Nominated.

Of these centres twelve have already been nominated, and will be recognized as National Radium Centres as soon as they have complied with the requirements of the Commission. Their geographical distribution is as follows: In England, seven centres (Birmingham, Bristol, Leeds, Liverpool, Manchester, Newcastle, and Sheffield). In Scotland, four (Aberdeen, Dundee, Edinburgh, and Glasgow). In Wales, one (Cardiff). The special case of London is referred to later.

In every instance the channel of communication between the Commission and the centre is the medical faculty of the local university, and loans of radium are being restricted in each area to one hospital selected by the faculty.

By these means, and in this way alone, has it proved possible to avoid the dangers and futilities of splitting up the limited national stock of radium into minute quantities, which would not only give ineffective results but contribute little if anything to a national, controlled, and co-ordinated study and practice of radium therapy.

The progress to date of the National Radium Centres varies considerably; local difficulties are more pronounced in some places than in others, and there are initial obstacles of many kinds to be overcome in setting up appropriate machinery for dealing with the novel and complicated problems involved.

The following centres, however, have now completed their organization and have been actually supplied with radium by the Commission: Birmingham, Cardiff, Edinburgh, and Aberdeen. Three other centres—Manchester, Glasgow, and Newcastle—will receive their radium almost immediately, whilst the remainder will be recognized and supplied as soon as the necessary preliminaries have been completed and the agreements executed. Negotiations to this end are still proceeding though their respective medical faculties.

In some cases the setting up of plants for the preparation of radon (radium emanation), with the object of supplementing the supply of radium, and of thus serving larger areas, has been approved by the Commission, and additional supplies of radium (in the raw) are being allocated to this purpose.

London's Special Problem.

London has been treated as a separate and special problem, in view of its position as the metropolis of the whole country. Here no centre of the normal type is being set up, but steps have been taken to organize two centres to carry out special work of general and national importance. One of these, the Westminster Hospital, has been experimenting, on behalf of the Commission, for several months past, with a "bomb" (containing 4 grams), in order to determine the value of mass irradiation and long distance radium therapy. The results of this work are not yet sufficiently determined to justify a public report, but this will be made in due course.

The other London centre which is being organized by the Commission is one for the development of *post-graduate* teaching in radium therapy—a prime and urgent need—and the facilities which will be provided will be available for the benefit of qualified medical practitioners from any part of Great Britain. This centre will be located at the Radium Institute and the Mount Vernon Hospital (Northwood), which institutions for these purposes are being reorganized as a joint teaching centre, styled the "Mount Vernon and Radium Institute," under a single control so far as medical services, teaching, and research are concerned. In all other respects the two institutions will retain their separate identities, but the treatment of patients, by radium or other means, will be greatly facilitated by the new scheme, in view of the increased amount of radium available.

Supplies and Records.

Summarizing the present position with regard to national radium, it may be stated that approximately 17 grams (out of a possible total of about 22) have been ordered by the National Trust and provisionally allocated by the Commission to national centres. Of this quantity, 9 grams have already been received from the manufacturers, and, after being tested at the National Physical Laboratory, 6½ of these have been actually delivered to centres and a further 3½ will be going out very shortly.

Another feature of the Commission's policy has been the preparation, in collaboration with the Radiology Committee of the Medical Research Council and the British Empire Cancer Campaign, of a set of "Radium National Forms" for the use of recognized centres, in order that the clinical records of all cases treated may be kept on a uniform basis and eventually incorporated in general national statistics. While the obligatory use of these forms is confined to national centres, it is hoped that they may eventually be adopted by other institutions practising radium therapy. Specimen copies may be obtained on application to the secretary of the Radium Commission at 5, Adelphi Terrace, London, W.C.2.

Scotland.

Health Estimates for 1930

THE detailed estimates for the cost of administration of the national health, labour, and insurance departments, issued on March 29th, show a decrease of £313,376 in the figures for the Department of Health in Scotland. An increase in the cost of administration amounting to approximately £39,000 is due mainly to the provision of extra clerical staff to deal with national health insurance, contributory pensions, and unemployment insurance work. Housing grants for 1930 are increased from £1,726,346 in the preceding year to £1,848,610. Various other grants show a substantial reduction owing to the fact that under the Local Government (Scotland) Act, 1929, these grants are now covered by Exchequer contributions to local authorities. The figures of the General Board of Control for Scotland show an estimated cost of £50,456, as against £92,079 in the preceding year, on account of the decrease in contributions towards the expenses of local authorities in providing for mental defectives. In consequence of additional clerical assistance required for the taking of the census in 1931, the office of the Registrar-General for Scotland shows an estimated increase from £16,367 to £17,264.

Transference of Lunacy Administration.

A circular has been issued by the secretary of the General Board of Control for Scotland, addressed to clerks of parish councils and district boards of control, expressing its appreciation for the manner in which the officials of the parish councils, soon to be superseded by new local authorities under the Local Government (Scotland) Act, 1929, have conducted their duties under the Lunacy Acts. The circular points out that since the Lunacy (Scotland) Act of 1857 parish authorities and inspectors of poor have carried out onerous duties in the treatment of the insane. Special reference is made to the success of the Scottish system of boarding-out in private dwellings those of the chronically insane capable of enjoying the amenities of domestic life. This boarding-out system, which is peculiar to Scotland, is stated to have been admired by alienists from other countries. Parish councils are requested to exercise the greatest care in the preservation of such records as would be of permanent use and interest, and to hand over all books, records, and documents to the new authorities. The success of the Scottish system of lunacy treatment to-day is attributed to the work done by medical superintendents of asylums and certified institutions, and by the staffs of district boards, during the last seventy years.

Spring Graduation at Aberdeen.

At the spring graduation at Aberdeen University, held on March 26th in the Mitchell Hall of Marischal College under the presidency of Principal Sir George Adam Smith, the honorary degree of Doctor of Laws was conferred on Professor Ashley W. Mackintosh, who recently retired from the chair of medicine in Aberdeen University. Fifteen medical graduates received the degree of M.B., Ch.B. In the course of his address the Principal remarked that the number of medical students at Aberdeen had increased from 266 in the previous year to 292, including 24 women. In the past winter the total number of students was 1,332 (861 men and 471 women), compared with 1,342 in the previous year.

New Health Services.

A memorandum on the reorganization of health services in Edinburgh, drawn up by the town clerk and the city chamberlain, was considered on March 25th by the Public Health Committee of the Edinburgh Town Council. It was pointed out that in Section 27 of the 1929 Act there was an implication that the functions of the Public Health Department were no longer to be confined to duties connected with preventive medicine, but might be extended to include the subject of general hospitals, a provision of increasing importance in future. A comprehensive scheme is apparently foreshadowed which will deal, not merely with the utilization of properties and institutions transferred to the town council under the Act, but involve consideration of the provision made by voluntary institutions

for sick persons. As existing institutions in Edinburgh serve, not only the city, but wide areas outside it, such a scheme may extend to the whole of the south-east of Scotland. It will therefore be necessary to consult other bodies, including outside local authorities, and representations have already been made by a number of voluntary agencies in regard to the part which they might take in such a scheme. The memorandum states that a scheme of the magnitude foreshadowed will involve new capital expenditure on a very considerable scale, and it suggests that the question of a State contribution should be considered during its preparation. In view of the forthcoming appointment of a new medical officer of health it was decided that no action should be taken until he had had an opportunity of studying the scheme. Dr. William Robertson, medical officer of health for Edinburgh, said that the new medical officer of health would probably have to direct the operations of a larger administrative unit, which would come into existence after May 16th, and that he would probably require an experienced assistant to act as deputy medical officer of health for the city. He also pointed out that the taking over of the parish council hospitals would not provide extra accommodation for the population of the city immediately, because the parish council authorities had been finding considerable difficulty in providing for the indoor treatment of their own patients. He thought that as higher standards were being set up by the Act of 1929, a matter for early consideration would be the provision of adequate cubic and floor space for the treatment of the sick.

Edinburgh Health Exhibition.

The health and hygiene exhibition promoted by the Public Health Department of the City of Edinburgh closed on March 29th. There were over 130,000 visitors in the seventeen days. In addition, about 4,000 school children were admitted free of charge during the last week. The scope of the exhibition was outlined in the *British Medical Journal* for March 22nd (p. 563). The total receipts, which include £3,000 of entry money, are estimated to exceed the cost of the exhibition by a considerable amount. Numerous health lectures on such subjects as milk supply, smoke abatement, venereal diseases, and ultra-violet light were delivered to large audiences.

England and Wales.

Leeds General Infirmary and the University.

THE cordial relations that exist between the University and the General Infirmary at Leeds have been shown at various times by reciprocity in the adoption of regulations affecting their administrative departments—for instance, the rule that the pathologist of the Infirmary must also be the professor of pathology. Since this rule was made the professor has shared with the assistant physicians and with others in the now greatly developed pathological department of the University and Infirmary the duty of conducting the autopsies. With the same underlying intention of binding the two institutions together the following new rule was passed at the annual meeting of the Infirmary on March 25th: "The academic consulting staff shall consist, *ex officio*, of the holders of the following appointments in the University of Leeds—namely, the professorships of anatomy, physiology, mental diseases, public health, and experimental pathology, and the lectureships on pharmacology and infectious diseases." The holders of these offices have from time to time given help and advice to the honorary staff of the Infirmary, but it is felt, however, that they should have some definite status in the Infirmary so long as they retain their posts at the University. Members of the honorary staff retire and become consultants when they have acted on the full staff for twenty years, or when they have attained to the age of 60: this practice is to be modified somewhat in the case of those in charge of special departments. Professorships in the clinical subjects, such as medicine, surgery, and midwifery, are always held by the honorary officers of these departments, but not under any rule, but because they commend themselves as the most suitable men for the positions. The retiring age for professors at the University is 65, but by a recent rule the University has wisely decided that when an honorary officer joins the consulting staff, whether in consequence of age or of length of tenure of office, he shall also retire from his teaching post at the University. In the development of the School of Dentistry important decisions made some years ago have been definitely consummated. Reference was made in these columns, on March 24th, 1928 (p. 518), to the opening of the new Dental Hospital, which was built by funds provided jointly by the University, the Dental Board, the honorary dental staff, and indirectly by the Infirmary, which gave the site. It was decided that when the hospital was opened it should, in its capacity as a teaching centre, be under the control of the University authorities, and, as a clinical institution, should become the dental department of the General Infirmary. The staff—the present holders being confirmed in their posts—are to be elected in the same way, and under the same conditions as to length of service, as the other members of the honorary staff, and they are to have representation on the board of management.

King Edward VII Sanatorium, Midhurst.

As in previous years, particular attention is paid in the annual report of the King Edward VII Sanatorium, Midhurst, Sussex, to the results of treating pulmonary tuberculosis by the induction of pneumothorax. In last year's report the results since October, 1924, were discussed, and now in the twenty-third annual report, which covers the period ending July, 1929, the record is carried a stage further. Cases in which this treatment was employed are grouped as follows: Choice I—Cases with involvement of one lung; Choice II—Cases with excavation or much evident fibrosis of one lung, or with involvement of the better lung not beyond the upper third; and Choice III—Cases with bilateral disease, and those *in extremis*—for example, with haemoptysis. The Choice II cases bring out an interesting point in prognosis, for it appears that in this group, when it has proved impossible to induce pneumothorax, in consequence of failure to find a pleural space, the prognosis is better than when the procedure has to be abandoned on account of adhesions. This suggests that, while thoracoplasty must necessarily be kept in mind in all Choice II cases where the induction of pneumothorax fails, it is more particularly urgent when this failure is due to the presence of adhesions. As would be expected, a steady increase is reported in the work of the *x*-ray department, which is largely concerned in watching the pulmonary condition after the induction of artificial pneumothorax. Details are given of a case in which complete re-expansion was eventually obtained, and also of another case of closed haemoptic bronchiectasis; radiographical illustrations are supplied. The number of patients discharged from the sanatorium to date is 5,312, and the statistical department continues to follow their subsequent progress. Various tables of prognostic interest complete the report, which may be obtained from the medical superintendent, price 1s., post free.

London County Council and Midwives' Training.

Several of the committees of the London County Council have furnished observations to the main body on the report of the Departmental Committee on the training and employment of midwives, which was presided over by Sir Robert Bolam. It is stated that the system of inspection advocated by the Departmental Committee is one which is already administered by the Council—that is, inspection by medical inspectors with special training in Midwifery. The Midwives Acts Committee states that it appears to be impossible to formulate a practical maternity scheme or to arrive at any accurate figures of cost until the intentions of the Ministry of Health, so far as London is concerned, are known, and suggests that the Ministry should be asked to consult the Council before promoting the legislation necessary to give effect to the Departmental Committee's recommendations. The Finance Committee also finds the position too vague at present to define the financial commitments involved in carrying out the recommendations; with regard to the

proposal to have a preliminary examination by local health authorities for women who desire to enter the midwifery profession, the Finance Committee assumes that arrangements would be made so that there would be no charge against the education account. The housing difficulty alleged by the Departmental Committee is commented on by the Housing Committee of the Council, which states that on the Council's housing estates preference is given as tenants to a certain number of such persons as midwives and nurses whose services are essential to the well-being of the community.

London Returns of Lunacy.

The total number of insane persons for whose accommodation the London County Council was responsible on January 1st (excluding those accommodated by the Metropolitan Asylums Board and the Poor Law guardians) was 21,034, an increase of 163 on the year. Of this number, 20,679 were in the London County mental hospitals, and 19,244 of them were rate-aided patients. In addition, the Metropolitan Asylums Board's institutions accommodated 4,370 chronic harmless patients (excluding cases dealt with under the Mental Deficiency Acts); 115 insane persons were resident in Poor Law institutions, and 92 were boarded out by boards of guardians. During the year there has been a slackening of the average admission rate, and an increase in the average death and recovery rates. These factors have tended to relieve to a small extent the pressure on the available accommodation in the county mental hospitals, which, however, remains acute, especially on the male side. Next year's figures will be awaited with interest, for the present report is the last in which it will be necessary to discriminate between accommodation provided by the Council and by the Metropolitan Asylums Board.

Correspondence.

INDIAN MEDICAL DEGREES.

SIR,—My friend Sir Thomas Carey Evans has made a strong and eloquent protest against the recent action of the General Medical Council in its dealings with the Indian Universities. May I put the other side of the case? It will, I believe, be accepted on all sides that the Council is in no way actuated by hostility towards India. Quite the contrary; but it has a definite responsibility for the maintenance of a certain standard of education in the lands where its writ runs, and it cannot, without betraying its trust, allow that standard to be lowered.

As a professor for many years in the oldest of the Indian universities, I am (like Sir Thomas Carey Evans) zealous for their traditions. Moreover, I consider that in some respects we were ahead of and not behind British standards in our teaching. The difficulties met with were, I think, not insuperable, and indeed they may even yet be surmounted. I refrain from discussing these difficulties because I feel that the least said on both sides will be the soonest mended.

One point more: it is a mistake to suppose that the action of the General Medical Council will really affect medical interests in India to any very great extent. It is certainly detrimental to the small percentage of Indian medical students and medical men who are aiming either at practice elsewhere in the Empire, or at perfecting themselves in their knowledge of their profession by post-graduate work or by taking extra degrees here in Great Britain. I am not belittling the loss it is to these men, and I sincerely sympathize with them in it, but I think Sir Thomas is too pessimistic in his view of the harm that this action of the General Medical Council has done or may do to the cause of Western medicine in India.

India has much to lose by cutting herself adrift from Great Britain in the matter of medical education, and it is sincerely to be hoped by every well-wisher of that country that no effort may be spared on both sides to overcome the present difficulties. In this I am wholly with Sir Thomas Carey Evans.—I am, etc.,

R. H. ELLIOT,
Lieutenant-Colonel, I.M.S. (ret.).

London, W.1, April 1st.

SIR,—The decision of the Executive Committee of the General Medical Council to recommend that the degrees of Indian universities in medicine and surgery be no longer registrable in Great Britain was not unexpected in India, and cannot, honestly, be said to be unjust. In face of the attitude maintained by the Indian politician, into whose hands, as a "transferred subject," medicine has passed, recognition on former terms was obviously becoming impossible. At the same time, it must be fully recognized that unless authorities in England take suitable action, grave injustice may be done to the better type of Indian graduate who comes to Europe for post-graduate instruction. Whether the degrees of her universities (some of which are very good indeed and some not so good) are registrable or not, the fact remains that India is a very important part of the Empire, and that her better and abler graduates look upon the United Kingdom as their natural headquarters for higher studies.

In discussing Indian educational problems with teaching authorities in England I have been told frequently that English medical schools do not want Indian undergraduates, as these ought to obtain their pre-graduate training in India, where there are ample facilities, but that Indians working for higher degrees and diplomas are very welcome. Medical schools in Great Britain, however, are very unwilling to accept for post-graduate work men whose degrees are not registrable in Great Britain, and the general result of the recent recommendation might be the closing of England to Indian graduates. The alternatives facing the Indian medical graduate are, either to go to England and to take a registrable qualification on arrival there, or to go to Germany or America for his post-graduate work. A distinguished American teacher said to me only a few days ago: "Your boys need have no grouch. Send them over to us. We shall be glad to have them." The tendency for British overseas subjects to go to America and the Continent for higher studies is to be deplored, and it is advisable, I think, to point out to Indian graduates, many of whom are members of the British Medical Association, how they may best and most rapidly obtain a registrable qualification after landing in the United Kingdom. For these registrable qualifications they must, of course, look to the great licensing corporations of England, Scotland, and Ireland. It is, I believe, the custom for these bodies to permit graduates of foreign universities, including Indian, to enter for their examinations immediately after arrival in England on presentation of certificates of courses of instruction—that is, their courses of instruction are recognized, but not their examinations. In certain cases when the licensing corporations are fully satisfied with regard to the adequacy of the first and second examinations of these universities, exemption is given for examination in anatomy, physiology, pharmacology, and materia medica, and, in some cases, from pathology and bacteriology. This is frequently done in the case of Indian graduates who wish to take the English Conjoint diploma, as it is generally admitted, even by G.M.C. inspectors, that teaching in these subjects is very satisfactory.

I suggest that the licensing corporations set forth immediately the terms on which they are prepared to admit graduates of Indian universities to their examinations. May I, in general terms, suggest the following:

"Provided that a graduate in medicine and surgery of an Indian university produces certificates covering all the requirements of the G.M.C.—including three years attendance on the practice of a general teaching hospital and the requisite experience in midwifery—he may be admitted to the final examination of the corporation concerned.

I suggest, further, that where a graduate has passed a degree examination in pathology and bacteriology, including practical work no further examination in these subjects be required.

The above suggestions are in strict accord with what I know to be the present practice of the English Conjoint Board, and the fact that the results obtained by Indian graduates in the examinations of that body are almost uniformly good fully justifies them. By making their exact requirements and examination facilities more widely known, the medical corporations of Great Britain will be doing a service to the Empire at a time when relations

with India are somewhat strained, and at the same time will guarantee that Indian graduates in Britain are adequately qualified to undertake higher studies. Of course, it must be distinctly understood that these remarks refer strictly to graduates of universities, and not to the host of diplomates of short-course schools, State faculties, and of the numerous other easy channels through which the medical profession may be entered in India.—I am, etc.,

March 17th. MEDIATOR.

ANTIMALARIA MEASURES.

SIR,—The letter of Sir Malcolm Watson in your issue of February 8th shows that the fundamental difference of outlook between the modern school of malariologists, as represented by Colonel James, and the old school, to which Sir Malcolm Watson belongs, is still as conspicuous as ever. I have no wish to revive an ancient controversy or to introduce personalities, but as this difference of outlook has exercised and is still exercising a baneful influence upon the prosecution of antimalaria measures it is necessary that the position should be frankly stated and the issue clearly defined.

As the result of the discovery some thirty years ago of the role of the mosquito in the transmission of the malaria parasite, malariologists not unnaturally assumed that they had discovered the key to the solution of the malaria problem. They stated, in effect, that if all mosquitos could be destroyed, malaria would be completely abolished. Nothing has happened or is likely to happen to upset the accuracy of this inference, but when it came to translating theory into practice it soon became apparent that great, if not insuperable, difficulties, administrative and financial, prevented any appreciable progress, except in specially favourable circumstances, being achieved along these lines.

In these circumstances malariologists—who may now be termed the modern school—came to the conclusion that the prosecution of further scientific research was necessary in order to discover whether new and more effective weapons might not be fashioned to supplement or to replace antimosquito and antilarva measures in those numerous instances in which malaria control by measures of this nature alone was impracticable. This view failed to commend itself to the old school, who stoutly maintained that the failure to achieve success by antimosquito, and more particularly antilarva, measures was due to apathy or incompetence, and they further held that all it was necessary to know about malaria was known—and that, as Sir Malcolm Watson stated before the Royal Society of Tropical Medicine and Hygiene in 1924, the time was gone "when patient and searching investigation and careful and continuous experiments" could serve any useful purpose in connexion with malaria control. Sir Malcolm Watson has, I believe, to some extent modified his views in this matter, but a perusal of his letter under reply shows that he has not materially changed his outlook. For him antilarva measures are still the sovereign remedy, quinine is useless, and social and economic conditions are of no importance. None of these ex cathedra statements receive support from modern research, and hence the wide divergence of view between the practical sanitarians and the scientific malariologists.

We thus have two schools—the one completely satisfied with the state of scientific knowledge attained some thirty years ago, and the other holding that as malaria constitutes an age-old problem of great complexity, its solution on a w[illegible] public basis is most likely to be achieved in the light of accurate scientific knowledge of its endemiology. The holders of [illegible] This difference of outlook would not be help and advice it not for the fact that the old school of it is felt, however endeavoured to establish their view-status in the Infirm[illegible] unsubstantiated claims regarding their of the University, their declamations, mainly in the lay and become consultant[illegible] pidity and ignorance of those who staff for twenty years, them.

age of 60: this practice once when I say that the harm the case of those in charg[illegible] ists of the old school of malario-fessorships in the clinical lay administrator says, "As we surgery, and midwifery, are hority that there is no more officers of these departments the interest of the taxpayer, further expenditure upon research." Can you blame him? He also says, "As we are likewise told, by the same high authority, that the only way to control malaria is to destroy all mosquitos, and we know, as practical administrators, that in our province the men, money, and material necessary for this purpose are not available, therefore, as practical men, we must conclude that medical science can do nothing for us, and that malaria must, in consequence, be regarded as an irremediable evil." We thus arrive at the logically illogical position that one of the chief apostles of malaria control has unwittingly become one of the chief obstacles to progress in a matter of vital importance to the health and welfare of the Empire.—I am, etc.,

Lahore, March 17th. C. A. GILL, Lieutenant-Colonel, I.M.S.

A DANGER FROM PARALDEHYDE.

SIR,—Not long ago I had occasion to order a dose of paraldehyde to be given to a young woman under my care in hospital. It was necessary to choose the rectal route, and half an ounce was injected along with three or four times its volume of water. The patient complained of great pain after the injection, and, later, considerable sloughing of the rectal mucous membrane took place. On inquiry it was found that the paraldehyde used had been largely converted into glacial acetic acid. I understand that this takes place according to the equation

$$CH_3CHO+O = CH_3COOH,$$

and as no water is formed in the reaction the product is glacial acetic acid, and that once a trace of this has been formed it acts as a catalyst, which may finally lead to the conversion of 75 per cent. of the paraldehyde into acid. If the paraldehyde is kept in an airtight bottle there is no risk of such a conversion, but if the bottle is not airtight oxidation will ultimately take place, with the above results.

I confess I had not known of this danger till the above unfortunate occurrence, and I thought that it might be worth while drawing attention to it.—I am, etc.,

London, W., April 7th. ROBERT HUTCHISON.

ANAESTHETICS IN MIDWIFERY.

SIR,—May I be allowed to analyse some of the criticisms of my letter of March 1st (p. 414) upon the above subject?

The controversy really turns upon the question whether a normal, straightforward childbirth is to be regarded as a physiological or as a pathological act. I hold that such a labour is purely physiological, and that by administering an anaesthetic to every case (except possibly for a short time towards the end) the risk arises of converting such a physiological case into a pathological one. That there is such a risk in a straightforward case of slowing down and sometimes suspending the normal uterine contractions, and thereby enhancing the possibility of ultimate instrumental delivery, cannot be denied; by eliminating the assistance of the patient's will-power, increasing the tendency to post-partum haemorrhage, and possibly having a deleterious effect upon the child, the administration of prolonged anaesthesia in every case would tend to raise rather than lower the maternal mortality.

Mrs. Baldwin suggests that the words "when necessary" in my letter "reveal the weakness" of my case, but I contend that they show rather the very essence of its strength, for surely it would be unjustifiable to administer an anaesthetic when it was not necessary. I cannot agree with the suggested practice of "giving an anaesthetic in every case in order to avoid shock," since it is common experience that a perfectly normal labour is wonderfully free from shock compared with one in which labour has been prolonged by the giving of an unnecessary anaesthetic. Just as for the poor, so also for the rich, the decision as to when an anaesthetic should be given must be left entirely to the discretion of the medical attendant. Mr. d'Avigdor is apparently not aware of the facts when he suggests that "it is obviously impossible for the midwife, when dealing with a case single-handed, to administer the anaesthetic and effect the delivery," or he would have known that any such attempt on her part would be an infringement of stringent rules. Dr. Bodman places the patho-

logical gall-stone and renal colic in the same category with the pain caused by natural uterine contractions fulfilling a normal physiological role!

If the fund is merely intended to assist those maternity hospitals which cannot afford to appoint an anaesthetist to assist with abnormal cases, well and good, but I adhere to my original contention that for any difficulties among the poor the Midwives Act provides ample facilities when necessary, and I deprecate the assumption that, while the rich can have anaesthetics on payment, the poor cannot have them because they are poor, with the veiled implication that doctors only do their duty in an atmosphere of fees. The question of financial status does not affect the situation if anaesthesia is the right treatment.—I am, etc.,

Lichfield, March 29th. F. M. ROWLAND.

LIPIODOL INJECTION INTO THE BRONCHI.

SIR,—Dr. Arnott Dickson, in his article on pulmonary tuberculosis (*Journal*, March 1st, p. 376), mentions two methods for the injection of lipiodol. He rightly discards bronchoscopy, but his own method of crico-thyroid puncture seems to me to be inferior to that employed by Dr. Haslinger of the Hajek Clinic, Vienna. As it is possible that this method is not generally known, a brief description of it may be of interest.

(1) The pharynx and larynx of the patient are first completely anaesthetized with a 20 per cent. solution of cocaine to which an equal volume of adrenaline has been added. (2) Using a laryngeal mirror and syringe a small quantity of diluted cocaine and adrenaline solution is injected into the trachea, and the patient is immediately tilted towards the side which it is proposed to examine. (3) A soft rubber catheter is passed through the nose into the larynx and well down the trachea. The protruding end of the catheter is then fixed to the ala of the nose with a piece of adhesive strapping. The position of the catheter is easily verified by mirror inspection, and by asking the patient to phonate. (4) The patient can now walk to the x-ray department, where it will be found that the bronchi concerned can be gently filled with the lipiodol under the screen, and the necessary films taken.

This method, I am convinced, will be found relatively agreeable to the patient and conducive to the deliberate examination that is so essential to success.—I am, etc.,

Aleppo, March 18th. E. H. R. ALTOUNYAN.

DIAGNOSIS OF PULMONARY TUBERCULOSIS.

SIR,—In connexion with Dr. Arnott Dickson's very helpful article on this subject, I should like to point out the great value of "single finger" or "hooked finger" percussion. By this I mean that the middle finger of the left hand is flexed at an acute angle at the proximal interphalangeal joint, the distal interphalangeal joint being hyperextended, and the pad of the finger applied to the area to be percussed. Percussion is then made on the flexed joint with the index or middle finger of the right hand. Light percussion in this manner in the intercostal spaces is extraordinarily useful in detecting slight degrees of dullness, especially in children. This method is mentioned both in Fishberg's *Pulmonary Tuberculosis* and in Hotder and Gow's *Essentials of Medical Diagnosis*, but its advantages do not seem to be generally appreciated.—I am, etc.,

W. E. ROPER SAUNDERS, M.R.C.S., L.R.C.P., D.P.H.

Cheyne-Street, March 22nd.

THE SIGMOIDOSCOPE IN COLITIS.

SIR,—I have read with interest the letter by Dr. A. G. Biggam (March 8th, p. 465), but cannot help expressing my surprise at his recommendation of the employment of the sigmoidoscope as an "essential procedure" in the routine examination of colitis. Such a procedure may be tolerated, and in a sense justifiable, in a native hospital, where a majority of the patients suffer from bilharzia, but to use such an instrument for the diagnosis of bacillary dysentery—concerning the nature of which no serious difficulty should at any time arise—appears to me to be unthinkable. If such methods of diagnosis were attempted in private practice the instrument would very soon get rusty for want of use, but fortunately there is little danger of its extended use, as the majority of physicians must agree with Dr. *Tidy, who not only has pointed out its dangers*, but also the fact that hitherto no information has been obtained that would alter the line of treatment based on other methods of examination. *It is obvious that a patient* nowadays must be very robust to be able to withstand the mechanical procedures considered necessary to establish a diagnosis.—I am, etc.,

Cairo, March 19th. T. GERALD GARRY, M.D.

MICRO-ORGANISMS IN PSITTACOSIS.

SIR,—May I appeal in your *Journal* for very thin, air-dried films of blood from cases of psittacosis in its early stage, or very thin films made from any of the organs, especially the spleen, in cases in which a section has been made?

During some recent work on blood films of this disease, kindly sent me by Dr. G. T. Western of the inoculation department of the London Hospital, I have been able to find, in very small numbers, some minute organisms of a diplococcoid form. Coccoid and diplococcoid bodies measuring about 0.3 to 0.4 μ in diameter, staining usually a reddish colour with Giemsa, are present in the blood of three human cases, and also in the blood and spleen of an inoculated hen and mouse. In all of these cases a short, thin bacillus measuring about 2 μ has also been detected, but only in very small numbers after a prolonged search. These, I think, are probably secondary invaders.

Films made from the spleen of an inoculated mouse show not only scattered minute cocci and paired cocci in comparatively large numbers, but also very definite and distinctive groups or small clusters of these organisms. These have a very definite appearance on account of their staining reaction with Giemsa and their remarkably sharp *outline*, and can be readily distinguished from other granules present. The clusters are usually free, but are sometimes found in the protoplasm of enlarged endothelial cells.

A paper giving full description and measurements will shortly appear, together with photomicrographs of the small masses of coccoid bodies as found in the spleen. The search for either of these forms in the blood of human cases is very trying, but it is possible that they might be present in greater numbers in the early stage of the disease, and it is for this reason that I have ventured to make my request.—I am, etc.,

Poole Road, Bournemouth, April 3rd. A. C. COLES.

Obituary.

JOHN YULE MACKAY, M.D., LL.D.,

Principal and formerly Professor of Anatomy, University College, Dundee.

IN our last issue we had to announce, with regret, the death of Principal J. Yule Mackay, the well-known anatomist, who for many years was intimately associated with the educational business of the General Medical Council. When he went to Dundee thirty-six years ago, University College had not yet been united to the University of St. Andrews, and he played a considerable part in the union of the two bodies.

John Yule Mackay, son of the minister of Inverkeithing, was born in the Manse there on January 13th, 1860. Receiving his early education in Glasgow Academy he passed to the University to study medicine, and in 1881 graduated M.B., C.M., with commendation, and in 1885 became M.D. Appointed assistant to Professor Cleland, and later lecturer in embryology, he spent twelve years in teaching and research before his appointment in 1894 to the chair of anatomy at University College, Dundee, in succession to Professor A. M. Paterson. His report on "The development of the branchial arches in birds" was printed in the *Philosophical Transactions* in 1888. His appointment as principal of University College, Dundee, in 1897, and in January, 1902, as representative of the University of St. Andrews on the General Medical Council, in which he became chairman of the Education Committee, imposed a burden of administrative work that left no

further time for research. In 1920 he was made a member of the Scottish Consultative Council on Medical and Allied Services. Failing health caused him, in 1925, to resign the professorship of anatomy, but the failure continued, and on March 30th he died, after a week of terminal illness.

In St. Enoch's Church, where Mackay had long been an elder, a funeral service was conducted by the Very Rev. Principal Galloway, and the interment was made in the cemetery at Barnhill. Principal Mackay was unmarried.

For the following appreciation we are indebted to Mr. JOHN TAYLOR of Dundee.

The death of John Yule Mackay removes from our midst one who in a rare degree possessed the warmest affection of all his students. Few university principals have been so popular. As professor of anatomy his geniality and kindliness had a profound influence on all those who were privileged to come into the closer personal contact afforded by his practical classes. Prior to coming to University College, Dundee, in 1894, Yule Mackay had endeared himself to all Glasgow medical students, and at this time his fame as a brilliant anatomist was world-wide. His embryological work, in particular that dealing with the development of the branchial arches, was characterized by an enormous amount of accurate detail. During those twelve years when he was working under Cleland at Glasgow he elucidated many obscure points relating to muscle and the peripheral nerves. But his whole time was not spent in research, for was he not the greatest of all Cleland's demonstrators? Yet he nearly chose botany for a career. He left many friends behind him in Glasgow, quite apart from his medical friends. Both the University Union there and the Students' Representative Council owed much to his zealous endeavours. In 1896, two years after leaving Glasgow, Mackay, along with his old chief Cleland, published the well-known *Textbook of Human Anatomy*, and some months later a *Directory of Dissection* appeared. No other textbooks of anatomy have the same conciseness, clarity, and grace of diction. We have no record of any other publication after his election to the chair of anatomy at Dundee. The only reason to account for this was that he had to give to administrative work any time not spent in teaching, for, after a year of service *ad interim*, he was appointed principal of University College, Dundee, in 1897. Stormy days lay ahead of him then, and he devoted himself to the question of the incorporation of University College in the University of St. Andrews. How often would he vividly recall the difficulties of those earlier days! An amicable agreement being reached in 1897 Mackay set his mind to developing the medical school. His anatomical department, extemporized from an engineer's old workshop, served him until, in 1904, a completely equipped medical school in Small's Wynd was opened. After this had been accomplished more students came to Dundee to study medicine, and many more came to study embryology under Mackay. The individual attention then given to the students afforded many advantages over the methods in other schools of to-day. But his administrative gifts were not confined

[illegible] twenty-eight years he represented [illegible] Medical Council, and as [illegible]ittee Mackay drafted and [illegible]edical instruction.

[illegible] lecturer, always [illegible] in a clear [illegible]ity were [illegible] day

[illegible] 13th, 1860. [illegible] Academy he [illegible] and in 1881 [illegible] and in 1885 [illegible] professor Cleland, [illegible] twelve years [illegible]atment in 1894 [illegible] College, Dundee, [illegible] on his report on [illegible]es in birds," was [illegible]s in 1888. His [illegible] College, Dundee, [illegible]ntative of the [illegible]dical Council, [illegible] Committee, [illegible]at left no

[illegible] played. As his senior demonstrator in anatomy until he retired in 1925 I have none but the most pleasant of memories. No one could have wished for a better or more courteous chief—a more genial senior colleague and friend.

THE LATE DR. P. S. HICHENS.

WE have received the following tributes from two former colleagues, supplementing the notes printed in our issue of April 5th:

D. G. G. writes: After he had left Northampton and gone to live in Guernsey, his friends had seen little of him. A few months ago he came back on a visit sadly changed by a long illness; he felt his invalid condition very keenly, and one cannot help assuming that, when death came [illegible] him, it was not altogether unwelcome. He came to Northampton on his appointment as physician to the General Hospital in 1901, having already gained distinction at Oxford and at St. Thomas's. A man such as he was could not fail to achieve success as a consultant, and, when he retired from the staff in 1924, he had a great reputation throughout the county as a physician. A public presentation was then made to him, and a portrait, painted by a local artist, was hung in the board-room of the hospital to mark [illegible] services to that institution. Hichens was a man of wide [illegible]neral culture: he had a sound professional knowledge, and, [illegible], and had withal a fine sympathy. To everyone [illegible] he came in contact he was courteous and [illegible] the paraldehyde aloof in his manner perhaps—sometimes rather [illegible] glacial acetic acid rather older than his years, possibly from [illegible] according to the old diction and choice of words, yet to all friendship was warm and gracious. In [illegible] $CHO+O = CH_3COOH$, nts and with members of our profession he [illegible]ed in the reaction of all. He had many activities. As a young [illegible] once a trace[illegible]n under treatment at Nordrach, and he worked very [illegible] for the provision of open-air treatment for tuberculous [illegible]nts. The institution of the sanatorium at Creaton owed [illegible] paralo[illegible] at deal to his efforts, and in it he took a legitimate pride. [illegible]rtight [illegible] relaxations were more artistic than athletic. He read widely [illegible] enjoyed music and painting, in both of which arts he was a good amateur performer. Outside his profession, however, his chief interest was in the Church. Brought up in a cathedral city—his father was Dean of Canterbury—he seemed in many ways as suited for the Church as for the profession of his choice. All his life was imbued with a religious outlook. He worked very hard in Church matters, was churchwarden of the Northampton Parish Church, and at one time a member of Convocation. He often addressed public meetings throughout the Peterborough diocese. While he had strong feelings in controversial matters, he always spoke his mind with tolerance, leaving his hearers with no doubt as to his views, but with no feelings of rancour. At the outbreak of the war he was a Major R.A.M.C.T.A., attached to the 1st Eastern General Hospital at Cambridge, and, although he was at that time above the age for foreign service and in some ways unfitted for it, he found means to be sent to France. He was at first in command of a casualty clearing station and was with the Fifth Army when disaster overtook it in 1918; after this he commanded a general hospital at Calais. His reserved manner made the life of the army more difficult for him than for most, yet he made many friends there, and his interest and zeal in his work were remarkable. He has gone from us and, look where we may, there is no one that can quite fill the same place that he did. He leaves a widow, a son, and a married daughter.

P. N. B. O. writes: I remember Hichens jokingly saying years ago that any obituary notice of himself would describe him as a physician "of the old school." This self-appreciation is in part true, if it means that he was a man of wide reading who had the English classics at his fingertips, a musician who had a sound knowledge of music and was himself a pianist above the average, and an amateur artist with no little skill with his paint-brush. Add to these that he was a true and thoughtful appraiser of anything that was beautiful in scenery, pictures, furniture, or china. What I think he meant to imply himself was that he was very conservative by nature, and that, while he would be among the first to make use of them, he rather regretted the introduction of new methods of diagnosis of treatment. Again, I always thought that he appeared [illegible]rent that the claims of increasing practice should not [illegible]isure for the enjoyment of his hobbies. He hated [illegible] that he was allowing himself to be too absorbed in [illegible]ssional work, of which he entirely disliked the com[illegible] and business side, to the exclusion of his many other [illegible]. That he was a very sound and most painstaking [illegible]an must be obvious from his record, and anything [illegible] have written in this short note must not be taken to [illegible]ct from this true estimate of his work. Rather do I [illegible] to insist that he was something more than a good doctor;

...ES GRIFFIN BEASLEY, who died on March 25th ... wley Regis, near Birmingham, at the age of 84, ... ae first medical officer of health to the Rowley Regis ... n District Council, a post which he held for nearly ... years. He was also police surgeon to the local ... -ion, medical officer to the education authority, and ... Law and vaccination officer for the Dudley Union. Beasley, who qualified L.R.C.P.Ed., L.R.F.P.S.Glas. ... 868, celebrated his golden wedding in 1920, and retired ... n a large practice in the following year, owing to ... ing sight. He was for many years a member of the ... tish Medical Association.

...Dr. EDWARD O'REILLY SOMERS, *who died recently*, was ... son of a former professor of materia medica at Owens ... lege, Manchester, and was born in 1863. He received ... medical education in Manchester, whence he obtained ... diploma M.R.C.S. in 1884 and the L.R.C.P. three ... rs later. After holding resident appointments at the ...nchester Royal Infirmary and the Salford Royal Hos... al, he began to practise in Pendleton, continuing there ... il his death. Apart from his professional duties, he ...k a keen interest in the public life of Salford, where ... was a magistrate and president of the Civic League ... Health. He was an ardent politician, and at the last ...eneral Election was chairman of the Liberal Association ... one of the Salford divisions. He was also president of ...he Playgoers' Club, the Manchester Shakespeare Society, ...nd the Bolton Shakespeare Society; he delivered numerous ...ddresses of great value on stage characters in *Hamlet* ...nd *Othello*, dealing with them from the medical stand... point and bringing out the psychological elements in these ...and other plays. In addition to his enthusiasm for Shake... spearean studies, one of the leading interests in his life ...was affection for French literature and the French people. ...He was a member of the Alliance Française, and an officer ...f the Legion of Honour; he took an active part in bring...ing to Manchester each year the players of the Comédie ...Française. His genial character and the wide range of ...his interests won for him many warm friends. He was ...a keen member of the Salford Division of the British ...Medical Association and a regular attendant at its meet...ings; he was almost invariably present at the Annual ...Meetings of the Association, and had proposed to make ...the journey to Winnipeg.

Dr. JOHN LANDSBOROUGH of Tighnabruaich, who died on March 20th, received his medical education at Edinburgh, where he graduated M.B., C.M. in 1895. After holding a resident appointment in the County Hospital of Ayr, and *spending some years in general practice in England*, he settled at Tighnabruaich, Kyles of Bute, about twenty years ago, being appointed parochial medical officer, and deputy medical officer of health for Kilfinan. He was a member of the British Medical Association. A colleague writes: Dr. Landsborough's practice was far-flung, embracing a long coast-line, from Loch Striven along the Kyles to well up Loch Fyne and Glendaruel. This involved the necessity of long journeys over dangerous roads, and of sailings, often by night, in stormy weather, but this all came to him as only "in the day's work." As he loved his work of healing, so these good Highland folk loved him, for he neither considered self nor selfish interests, his one thought being to "mind" his flock. The work was hard, the financial returns small, but he was never known to whine or grumble. He would only smile at the mention of money. His clinical skill and acumen were remarkable, and he ever had some medical problem or other in his thoughts, until he found its proper solution. He was undoubtedly, for these twenty years, an integral part of the character, life, and landscape of that rugged but picturesque part of Argyllshire. A man of culture and refinement, he was ever philosophical in his outlook on life, as might be expected in one who was at the same time a true son of Hippocrates and of Isaac Walton. Many years will pass before his memory fades among the men, women, and children of Cowal, but especially to the mothers and the bairns will his passing be almost irreparable, for he was cast in the same mould as the doctor in Ian Maclaren's *Beside the Bonnie Brier Bush*.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Housing Bill and the Housing (Scotland) Bill were both set down for second reading in the House of Commons this week, and the financial resolutions relative to these bills also came before the House. The closing stages of the Unemployment Insurance Bill were taken, and on April 11th the Mental Treatment Bill was down for report and third reading.

The Parliamentary Medical Committee and the Parliamentary Science Committee, at a joint meeting on April 8th, were addressed by Mr. Coste, chemist to the London County Council, on sewage disposal. On the same day the Parliamentary Medical Committee, in view of the coming Budget, briefly discussed the tax allowances for doctors' motor cars.

Mental Treatment Bill.

COMMITTEE STAGE CONCLUDED.

On April 3rd consideration of the Mental Treatment Bill was completed by a Standing Committee of the House of Commons.

The second schedule of the bill enumerates and describes powers under the Lunacy Acts, 1890 and 1891, to be transferred to the Board of Control. These include power to determine whether a hospital desiring registration should be registered, and to approve agreement by local authorities to unite for provision of mental hospital accommodation. Miss LAWRENCE said the matters of administration specified in the schedule were now dealt with by the Board of Control first and the Ministry of Health after. It was proposed to transfer them to the Board under the general oversight of the Ministry. Dr. VERNON DAVIES asked if the fact that the bill had to be read in conjunction with the Lunacy Act would not create difficulties for the medical profession. Miss LAWRENCE replied that the Lunacy Act itself required co-ordination and revision. She admitted that the present small amending bill had the vice of legislating by reference. Mr. GREENWOOD said the transfer of the powers mentioned in the schedule had been recommended by the Board of Control. The Board would always act in consultation with the local authorities.

An amendment by Mr. MORRIS-JONES was withdrawn, and the schedule was added to the bill.

The third schedule enumerates matters with respect to which rules may be made by the Board of Control. After the committee had made consequential amendments, Mr. GREENWOOD moved to add to the list the following matters:

"4. Applying to temporary patients received under Section 5 of this Act, subject to such modifications and adaptations, if any, as appear to the Board to be necessary or convenient, the following provisions of the principal Act, that is to say, Section 40 (which regulates the use of mechanical means of restraint), Section 41 (which relates to the letters of patients), Section 42 (which relates to the posting of notices), Section 47 (which relates to the visits of friends), Section 49 (which empowers the Board of Control to order the examination of a patient by two medical practitioners), Section 50 (which relates to inquiries as to property), Section 51 (which relates to searches in the records of the Board of Control), and Section 85 (which provides for the retaking of patients who have escaped).

"5. Modifying and adapting, in relation to institutions maintained by local authorities not being mental hospitals, the provisions of Sections 275 to 278 of the principal Act (which relate to the making of general rules and regulations and the appointment and duties of certain officers)."

Mr. Greenwood said the first paragraph had been inserted as a result of representations that the provisions set out in it from the principal Act and which now applied to certified patients only should be applied, with the necessary adaptations, to temporary patients received under Clause 5. It might be that these precautions were not necessary in many cases. The words here were being inserted as an additional safeguard to the patient. Para. 5 was consequential on an amendment made in Clause 6 (5) of the bill.

Dr. VERNON DAVIES was not prepared to agree entirely with the contention that these words were an additional safeguard to the patient. They would put temporary patients under all the regulations and restrictions of certified patients. He thought the provision regulating the use of mechanical restraint should be in the bill. That which related to the letters of patients did not appeal to him in the same way. The provision which empowered the Board of Control to order the examination of the patient by two medical practitioners was important. It might be applied in the case of a temporary patient who was kept on as such but who should be certified. The authorities would be acting illegally in keeping a definitely certifiable patient as a temporary one. The committee should squarely face the fact that the only difference between a temporary patient and a certified lunatic was that the former had a hope of recovery, and consequently was not certified.

Mr. GREENWOOD said he could not accept that view. Section 49, which provided for a patient to be examined, did not necessarily

mean certification. The Commissioners might order the patient to be discharged. Without the words he proposed the safeguards for the temporary patient would be less than for certified persons.

Dr. MORRIS-JONES agreed that, though the amendment appeared formidable, it was needed in the interest of the patient.

The committee agreed to the amendment and to the schedule, as also to the fourth schedule—"Repeals"—with consequential amendments.

This finished the work of the committee, and the bill was reported to the House. Subsequently its report and third reading were set down for April 11th.

The Army Estimates.

On the motion that the House of Commons should go into committee on the Army Estimates, on March 24th, Mr. SHAW expressed his regret that there was a shortage of medical men who were prepared to undertake a career in the Army. Although the physical tests had been scaled down, the Army as a whole was still under establishment. Out of a total of 72,268 recruits who presented themselves for enlistment in 1929, 23,131, or 39 per cent., were accepted, and 61 out of 100 were rejected even on the standards now insisted on. Of the rejections 91 per cent. were on physical and medical grounds. The lower dental standard, which had previously been tried in Scotland, had been extended to England and Northern Ireland, and by that means an additional 2,384 recruits were enlisted for all arms. In December, 1928, the height standard for the infantry of the line was lowered to 5 ft. 2 in., and 3,219 recruits were accepted who would otherwise have been lost to the Service. Without them, the intake for 1929 would have been only 24,840. The physical condition of the young men who presented themselves was a serious matter. He was asking his staff to investigate how far that physical deterioration was due to industrial depression, or to other causes.

Dr. FREMANTLE called attention to the fact that the medical service of the Territorial Force had been cut down to a point at which it would be difficult to expand it in time of active service. He said that the same thing had happened before the Crimean war and the South African war. In those cases, when war broke out the arrangements had collapsed, and then the Director-General of the Army Medical Services had been blamed, when the blame had really rested with the War Office and Parliament. In 1902, after the South African war, an Army Medical Service Departmental Committee went into the matter thoroughly. He (Dr. Fremantle) knew a good deal about it, because he was the assistant secretary to the committee. The committee was presided over by the then Secretary of State for War. Practically every reform which was suggested was introduced, with the result that there was an extraordinary improvement in the Army Medical Services right up to the late war. Adequate attention, however, had not been paid to the Territorial Medical Service. This matter should be taken into account, and he hoped that every Territorial field ambulance would be extended to three sections. One service after another was complaining of the shortage of medical officers. The Secretary of State for War had stated that there was still a regrettable shortage of candidates for the Regular Army, and that the supplementary officers and the Officers' Reserve were much below establishment. Only four years ago Sir Richard Luce, who was then a member for Derby, speaking on this subject, remarked that the establishment of medical officers was 900, and that the strength was only 794, a shortage of 106. The present establishment was 589, and the strength only 533. The British Medical Association felt that the War Office had treated it fairly in accepting its suggestions, but still the Government had not the men coming into the Service. Parliament had to consider, when trying to attract young students or medical men into the Service, that these men were looking to the future. A medical man came out of the Army, say, at 45 years of age, with a pension of £1 a day. What was he to do if he had a wife and children, and little chance of getting other work? Sufficient attention was not paid to the outlets from the Service. The Government was a large employer of medical men, and had many services in its different departments which required senior men, who often had to be brought in from outside. Under the Local Government Act passed last year the municipalities would need other senior medical officers. The Government had great influence and the power of the purse. If it would use its influence in helping in the selection of suitable candidates as medical officers of health it would give a considerable chance to officers who, having served their time in the Army, would thus be able to get a start in civil life. So long as medical services served on terms equal to officers of the combatant services, young men of enterprise, who liked to see the world, would be attracted, and they would come in for five, seven, or ten years. These young men, however, must be given an opening in civil life afterwards. The War Office ought not to rely on keeping these men on after their time had expired to carry on the work which ought to be done by younger men. These men became discontented. Dr. Fremantle recalled that in 1904, when the Army Council was set up, the one proposal of the Departmental Committee which was not accepted was that the Director-General of the Army Medical Services should have a seat on the Army Council and be responsible, as he was not at present for the whole of the equipment and organization of the medical service. That was a technical question, which could not be dealt with on this occasion. In essence that idea remained the fundamental belief of all successive Directors-General of the Army Medical Services. He hoped the Secretary for War would go into the matter again, because it had a considerable bearing on the efficiency of the medical service. That efficiency was vital to the future of the Army, for whatever purpose the Army was required.

Mr. SHAW assured Dr. Fremantle that he did not look on the matter with equanimity. Whereas the authorized establishment of the R.A.M.C. was 846 officers, there was a deficiency of 111, so that where they needed 7 doctors, roughly they had 6. He personally was willing to take the matter back and have it reconsidered by the Army Council in every way.

The Civil Estimates.

On the Civil Estimates, in the House of Commons on March 31st, Sir KINGSLEY WOOD raised the question of maternity and child welfare. He said that so far as infantile mortality was concerned the country could congratulate itself on the position, but the state of the maternal mortality rate was nothing like so encouraging, and provoked a considerable amount of disquiet. A great improvement in the carrying on of the work in connexion with these two matters would be obtained by transferring it from the smaller local authorities to the larger bodies like the county councils. With larger authorities they had the school medical service. If they could co-ordinate the work in connexion with maternity and child welfare, and link it up with the larger authorities, they would place that work on a level with the school medical service of the local authority. That would be a very great gain, which would be lost if they relied on the smaller local authority. They would practically have continuity in the supervision of the health of the children from birth up to the school-leaving age. He hoped the representative of the Ministry of Health would assure the House that the Ministry was going to assist in every way it possibly could the work both of the local authorities and of the voluntary agencies.

Miss LAWRENCE, in reply, said that it was stated that special money was required for infant welfare. That was one of the services which had to be taken away from proportional expenditure and had been placed under the block grant, which was stereotyped for a term of years. They could not give any more money for that purpose unless they tore up the Act of 1929. The average figure of maternal mortality had remained steady for a period of years over the whole country. Some years it fluctuated up and sometimes down. There were two committees dealing with the question. One was the Departmental Committee on Medical Research, which had already received confidential reports on individual cases. That committee was on the point of making a report. The second committee was dealing with the training and assistance of midwives, and had already reported. That subject raised a large number of questions of considerable difficulty, which would involve further legislation. The great difficulty was to obtain proper maternity services for ante-natal clinics and advisory clinics, and more co-operation on this subject was wanted between national health insurance work and the work of the local authorities. The matter was receiving the attention of the Ministry, but the question of legislation had not been fully explored up to the present by the Ministry of Health. There was no form of health work where the results in proportion to the expenditure were more gratifying than that of advice to expectant mothers. The work of public education in this matter was very important. The percentage of expectant mothers who attended antenatal clinics in Woolwich, where there was a really good publicity propaganda, was 40 per cent. The percentage in Bermondsey was 35, in Bristol 27, in Manchester 13, and in Gateshead 15. The problem was not insoluble. It raised very intricate questions which Parliament would do well to consider. If the local authorities would use their powers to the full and conduct a proper campaign of public education to bring up the level of the backward authorities to that of the best, we should see, not a complete solution, but a very gratifying improvement in this service.

Mr. MELLER urged Miss Lawrence to consider the development of the maternity and child welfare clinics, and not to attach too much support and co-operation under the national health insurance scheme. He said that too much stress was laid on this point, and that there was a greater desire to get hold of some of the money for the pockets of the doctors than to provide the health-giving services, which should be the main object.

Major GLYN remarked that he did not want to say anything against the medical profession. It was known what wonderful work was done by doctors, but he often felt that, since the panel system came into force, there had been an inclination on the part of some doctors rather to lie back and not keep up the high traditions of their profession. One of the most important things with regard to educating the community was to give that public sense of the

decencies of life which a man must contribute towards his wife. There was no doubt that many cases of maternal mortality and infant death were due to the selfishness of the husband. It was not a matter for the medical profession, but for public opinion. If possible, perambulating clinics should go in motor lorries to isolated villages and be available to explain to married women the main principles of the ordinary rules of life which people in cities could obtain by going to clinics.

Dr. VERNON DAVIES said that he regretted that the debate seemed to have developed into a more or less underhand attack on the medical profession. For an effective maternity and child welfare service they must have doctors. The maternity service of a medical man was an extremely onerous service. He had attended hundreds of confinements for ten days, and stayed up all night, for a guinea. He would not like to start again. They would find that practitioners were not now inclined to give their time to this work, and there was a tendency for the maternity service to get into the hands of particular doctors and certified midwives. That was a move which had the hearty sympathy of all medical men, because there was no doctor who had anything of a practice who could afford to spend hours on end waiting for some poor woman to be delivered of a child. It was better that certified midwives should attend to cases which lasted so long; they could send for a doctor if necessity arose. Unless the medical man and the midwife were adequately remunerated there would not be an effective maternity service. The question of maternal mortality was one of the greatest tragedies in the life of the nation to-day. Yet the peculiar thing was that it was not of necessity that they got these puerperal cases in the slums. Puerperal fever did not depend on slums, although they naturally did not want women to give birth to children in the slums. There was a tremendous shortage of beds for maternity cases in the country. According to the last report of the Ministry of Health, there were 2,480. It seemed appalling that there should only be that number for nearly 670,000 births. A method which could be much extended by the Ministry of Health through the local authorities was that it could take over, not what he called municipal maternity homes which were coming into existence, but large houses which had become more or less derelict. If these were made available as maternity homes they would prove a great boon. The need for ante-natal work had now become very well recognized, but here again the whole success depended, first of all, on the doctor, and, secondly, on the nurse. Education and propaganda were needed, so that the women of the country, especially the young married women, should realize that it was to their advantage, and to that of their babies, that they should be examined as early as possible in pregnancy, so that if things were not in order precautions could be taken. There was a committee sitting to inquire into the training of midwives. He believed that the Ministry of Health had some idea of either doing away with or relaxing some of the regulations of the Central Midwives Board. That would be a retrograde step. The Central Midwives Board had done extraordinarily good work, and was doing that work to-day. It should be the duty of the Ministry, instead of handicapping that institution or interfering with it, to do all it could to encourage the Board in its work. It was also necessary to see that there was efficient after-care, and that there were competent health nurses. He was glad that the Ministry of Health insisted that health visitors should possess the health certificate, but there was one great danger which applied to health visitors as well as to other nurses. It did not necessarily follow that the person with the best certificate, or with the largest number of degrees, was the best person for the work. There were such things as professional tact, common sense, and motherliness. Another point on which the Ministry might exercise a certain amount of control was the feeding of children. This country was perhaps not so far advanced as it should be in the matter of pure milk. Every effort should be made to see that women suckled their own children, because mother's milk was best for the child. The Ministry might concentrate more than it did on the question of pure milk. It could pay more attention to the unsweetened condensed milk, which was imported from the Continent in huge quantities, and which the late Minister of Health said was not fit for babies. People bought this milk because it was cheaper than ordinary milk, and in many districts children were being fed on milk which was found to do them harm. This condensed milk from abroad should not be allowed to be sold retail in less than 7 lb. tins. That would immediately stop the sale of the 4-ounce tins, and people would be compelled to provide one of the dried milk foods, or, better still, pure milk from the cow. Our milk supply required looking into. The amount of adulteration which went one was a disgrace to our civilization, and very often they found in the more residential towns the worst milk supply. Surgical tuberculosis in children, one of the most dreadful of complaints, was undoubtedly due to tuberculous cow's milk, yet how often was the milk examined for tubercle bacilli? There was tuberculin-tested milk, it was true, but ordinary people could not afford to pay for it. The first duty of the Ministry of Health was to see that the children were started well and were fed with tuberculin-tested milk to give them a chance of a good start in life. Another subject in connexion with maternity and child welfare centres was the very vexed subject of birth control. He hoped that the Government would persist in the attitude which it had adopted up to now, and would refuse to instruct any of their medical officers at the centres to give information on the matter.

Miss RATHBONE said that she hoped that the Ministry of Health would very quickly put part, at any rate, of the report on midwifery training into practice. The midwifery service was extremely ill paid. Many of them doubted the wisdom of the recommendation in the report that would place the whole onus of training, and of preparing the syllabus for the training of midwifery on medical officers of health rather than on the Central Midwives Board. There was always the fear that the medical officers of health had too little practical experience in this kind of work, and were too much under the thumb of local medical opinion.

The Housing (No. 2) Bill.

The Housing (No. 2) Bill, which was introduced by Mr. Greenwood and set down for second reading in the House of Commons this week, does not abolish the "Wheatley" Act for the erection of houses with a Government grant. It applies to England and Wales. Its chief object is to enable local authorities to clear the worst slum areas and to improve other areas which at present threaten to lapse into slums. "Clearance areas" are to be defined substantially as "unhealthy areas" are under the present law. Local authorities may purchase and clear, or require the owners to demolish the slums. Rehousing will normally be on other sites, but may, exceptionally, be on the cleared site. The grant proposed is normally 45s. per person displaced and rehoused. In agricultural parishes the grant will be 50s. a person, and in cities where persons have to be rehoused in tenements of more than three stories 70s. Each housing authority must present a five-year programme to the Minister of Health. Modifications are proposed to simplify and expedite the law relating to the repair or demolition of insanitary houses not in a scheduled area. The tribunal of appeal is to be the county court.

The Housing (Scotland) Bill, presented by Mr. Adamson, similarly proposes to deal with clearance areas, with improvement areas, and with individual insanitary houses. Grants may also be paid to hostels provided for single men by local authorities. Scottish housing authorities will also have the duty of reviewing housing conditions in their districts and to submit proposals to the Department in 1930, 1933, and each fifth succeeding year.

Under Mr. Greenwood's bill Government grants may be made to a voluntary housing association through a local authority. No such provision is included in the Scottish bill.

Mr. GREENWOOD moved the second reading of the Housing Bill on April 7th. He said it was short-sighted to spend money on health services and at the same time to condemn people to live under conditions which created the disease to deal with which the health services were brought into existence. When the time came that every overcrowded family had a decent home the nation would rid itself of a burden of disease, misery, and degradation.

Mr. CHAMBERLAIN said the Conservative party would support the bill.

Dr. FREMANTLE said that the bill was long overdue. As a past-president of the Society of Medical Officers of Health, and as one who, before the war did perhaps as much as anyone to bring before his colleagues in his profession the necessity for dealing with the housing problem, he spoke on their behalf, though without direct mandate, when he said that they wished the greatest measure of support to be given to the bill in general, and at the same time the most meticulous criticism of its details in committee. They must be perfectly frank in dealing with the problem. It was useless to compare the vital statistics of one slum area with those of the area surrounding it. People lived in the slums by reason of bad fortune of one kind or another. It was often a case of mental deficiency, heredity, and poverty. One of the greatest merits of the bill was its continuity; it really preserved a general continuity in regard to housing measures which were gradually getting to work. Medical officers of health looked forward to the result of the census of next year, which would tell exactly the state of overcrowing compared with 1921. They would then have definite data on which to proceed. Meanwhile, all the reports of medical officers went to show that there was an improvement in housing accommodation, although there had been a great change in the transportation and disposition of population. There had been a greater gravitation towards Greater London, which had made the position in London more difficult. The same was true of other big centres. The bill was supposed to enable them to close houses and to demolish slum areas, and at the same time to build houses. He hoped that it might be so. Medical officers of health had been working for a long time on this question of closure and demolition of houses. Closing and demolishing orders had unfortunately been a dead letter since 1914. The result was that in a recent report from the medical officers of health in England and Wales it was shown that of 2,500 houses recommended for closing and demolition only 500 were demolished. That was

because there was not a sufficient supply of new houses. No measure—not even the present bill—would be any good unless it helped to provide new houses in which to rehouse persons removed from the slum areas. One very material reason for delay in clearing slum areas was the Rent Restriction Act, which was not dealt with in this bill. Medical officers of health would welcome certain parts of the bill. In Clause 17 there was a very valuable power, which enabled part of a house to be closed without closing the house altogether. There were also valuable provisions in the improvement clause, which was really the only novelty in the bill. The provision for the aged should be extended. The method of subsidy was a valuable feature. It attacked overcrowding, which was really the greatest difficulty of all.

The bill was read a second time.

Position of Pharmacists in Poor Law Hospitals.

On the motion for the adjournment of the House of Commons, on March 31st, Captain GUNSTON called attention to the position of pharmacists in Poor Law hospitals under the Draft Poor Law Order published by the Ministry of Health, and now called the Public Assistance Order, 1930. He said that pharmacists were very much concerned about the Order, because they felt that the status of members of their profession employed in Poor Law hospitals would be seriously jeopardized. He asked that the Ministry should allow a local authority to make the pharmacist a principal officer if it wanted to do so. They did not ask for more control, but simply that these matters should be left in the hands of the local authorities.

Miss LAWRENCE said that if that were all that was asked she could answer "Yes." This was not a new Order. It was an old Order, reissued and reprinted—nothing more. There was no modification of substance. The only modification was the verbal one necessitated by the change in the names of the new authorities. If local authorities desired that a pharmacist should be a chief officer they could recommend the matter to the Minister and discuss it with him, and even appoint him as chief officer before the Minister examined the question. The assurance was given to the local authorities by the previous Government that any amendment or modification with regard to superior officers should not be made until after consultation with the authorities. If any amendment was desired it could be made subject to consultation with the local authorities. The Ministry had changed nothing. They had not made it impossible for these people to be appointed. In these matters, as in every other, they had left the position as it was, for consultation with the new authorities.

Tuberculin-tested Cows and Agricultural Shows.—Mr. GREENWOOD made a statement to Mr. Ramsbotham, on March 27th, regarding the order prohibiting the exhibition at shows of animals from tuberculin-tested herds. He said some of the bodies organizing agricultural shows were now prepared to arrange for the segregation of animals belonging to licensed tuberculin-tested herds, and he had promised to see their representatives with a view to considering the withdrawal of the prohibition in shows where effective provision was made for this purpose.

Psittacosis.—Mr. GREENWOOD told Mr. White, on April 3rd, that the Ministry of Health had received information of twenty cases of illness which commenced last month and in which the patients had been associated with parrots. In the present state of knowledge it was impossible to say definitely how many of these persons were suffering from psittacosis. This was not a notifiable disease.

Vaccination of Small-pox Suspects.—In a reply, on April 3rd, to Mr. Groves, Mr. GREENWOOD said he knew that doctors in the service of the Metropolitan Asylums Board vaccinated children sent to the shelters as suspected cases of small-pox, and that this was done without reference to the wishes of the parents or the fact that many of the children had been legally exempted from vaccination. The vaccination was solely in the interests of the children, who whilst under observation were exposed to small-pox infection at the shelters, in order that they might be protected against an attack of that disease if they had not already contracted it. It would not be desirable, in view of the risks involved, to make any exception to this practice. He had no authority to issue instructions that no child taken to the hospitals or shelters of local authorities should be vaccinated without the consent of its parents.

Silicosis.—Mr. SHORT, on April 1st, told Mr. Millar that the Home Secretary was not satisfied, on the evidence at present before him, that there was any sandstone quarry to which the Silicosis Order applied, in Scotland or elsewhere, in which there was no risk of silicosis. The medical inquiry into silicosis among sandstone workers, arranged for by the Home Office and Mines Department in 1928, extended to Scotland, and disclosed cases of silicosis in every area in which examinations were made, and showed that quarrying was among the dangerous occupations. Fuller information would be obtained from the medical examinations now being made at quarries by the medical board set up under the scheme. The Home Secretary intended, when these were completed, to review the position.

London Lock Hospital.—In a reply to Mr. Ernest Brown, on April 3rd, Mr. GREENWOOD said the governing body of the Lock Hospital had given effect to a large number of the recommendations contained in the papers presented to Parliament last July. Further improvements were in contemplation. The interests of the hospital would not be served by detailing at present the reforms effected. The board of management of the hospital included six women.

Health of the Mercantile Marine.—On April 1st Mr. GRAHAM told Mr. T. Lewis that the committee set up to consider and advise on questions affecting the health of the mercantile marine had in hand a detailed investigation into the question of how far and in what way the statistics relating to the mortality of seamen could be improved. The committee would inquire into the deaths reported month by month, from October last probably until September next. No report could therefore be expected for some months. Work on the hygiene of crew spaces on board ship was well advanced.

Sickness Certificates under the National Health Insurance Act.—On March 31st Miss LAWRENCE told Sir Kingsley Wood that the issue of sickness certificates under the National Health Insurance Act had been under discussion with representatives of those concerned for a considerable time. The draft of a new regulation with respect to this issue would be published at a very early date.

The Services.

THE GILBERT BLANE MEDAL.

THE Gilbert Blane medal has been awarded this year to Surgeon Lieutenant Commander J. F. H. Gaussen, R.N. The medal, which was founded in memory of the late Sir Gilbert Blane, is awarded annually to the medical officer who obtains the highest aggregate marks at the examination for promotion to the rank of surgeon lieutenant commander.

DEATHS IN THE SERVICES.

Lieut.-Colonel Eric Harding Sharman, Madras Medical Service (ret.), died suddenly in a nursing home at Bournemouth on March 5th, aged 64. He was born on July 21st, 1865, the son of the late Mr. Eric Rudd Sharman of Liverpool, and was educated at Westminster Hospital. After taking the M.R.C.S. and L.R.C.P.Lond., in 1890, he filled the posts of senior house-physician, house-surgeon, and clinical assistant in the skin and throat departments at Westminster Hospital, and of house-surgeon to the Hospital for Sick Children in Great Ormond Street, London. He entered the I.M.S. as surgeon lieutenant on July 29th, 1893, became lieutenant-colonel on January 30th, 1913, and retired on August 1st, 1913. In 1901 he took the diploma in tropical medicine of Liverpool University. He served in the China war of 1900, receiving the medal, and rejoined for service in the war of 1914–18.

Universities and Colleges.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examination indicated:

M.D.—J. F. O. Bodman, T. F. R. Hewer.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examination indicated:

M.B., B.Ch.—Isabel M. Adam, J. M. Alexander, *G. H. Bell, D. C. Brodie, G. H. Campbell, L. Charmatz, T. Crawford, A. N. Currie, D. W. Dewar, A. Duff, C. N. Gibb, A. Gibson, J. S. Gillies, W. Gunn, ‡J. F. Hegan, A. S. Henderson, S. T. Henderson, D. Jacobs, M. K. Johnston, Helen M. Keith, †R. Kirk, W. R. Logan, G. M'Dougall, J. A. M'Farn, D. M'Ghee, N. S. R. MacGregor, D. A. M'Intyre, J. B. L. M'Kendrick, Mary Nicolson, J. Paddin, F. B. Proksch, Hanna Birkalla, J. R. Robertson, D. Ross, Agnes A. S. Russell, J. G. Scott, A. Seton, A. M. Spence, Mary F. Tanner, D. W. Walker, A. B. Wallace, A. Young, T. M. Young.

* Distinction in surgery and midwifery.
† Distinction in medicine and midwifery.
‡ Distinction in midwifery.

NATIONAL UNIVERSITY OF IRELAND.

UNIVERSITY COLLEGE, DUBLIN.

THE following candidates have been approved at the examinations indicated:

D.P.H.—*Part I:* *P. J. Deery, *P. Keane, *M. M. J. Maughan, [illegible] nne, M. Kirby, Mary P. Moloney, O'Gorman, J. O'Neill, Margaret H. [illegible].

* First-class honours.
† Second-class honours.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

AT the monthly business meeting of the College, held on April 6th, the following candidates nominated on January 3rd were duly elected Fellows: David Gray, Ninian M'Intire Falkiner, Edward Thomas Freeman, Victor Ormsby M'Cormick.

The following, having passed the Final Conjoint Examination held in March, were duly admitted to the Licences in Medicine and Midwifery: J. H. de Villiers, D. Dorgan, V. J. Fielding, T. S. Harbison, J. E. Lewis, J. Lewis, Doris F. Weir.

Medical News.

ON Friday, April 18th, at 3 p.m., the Glasgow and West of Scotland Branch of the British Medical Association will give a reception, in the Students' Union of the University of Glasgow, to the students graduating in medicine on the following day.

THE house and library of the Royal Society of Medicine will be closed from Thursday, April 17th, to Tuesday, April 22nd, both days inclusive.

MR. SOMERVILLE HASTINGS, Dr. Salter, Dr. Ethel Bentham, about forty medical men who are not M.P.s, and two dentists met at the House of Commons on April 7th and adopted a constitution for a proposed National Medical Service Association. The constitution states that the association is to be independent of any political party. Membership is to be open to all registered medical men and women and dentists and to registered medical and dental students, and to such others as are in sympathy with its objects, and are invited to join by the executive committee. The association is to "advocate and make clear to the medical profession and to the public the advantages of a National Medical Service. For this purpose it shall from time to time hold public meetings, publish and circulate literature, and otherwise promulgate its cause. The association shall take all necessary steps to promote and secure legislation giving effect to its objects." *A footnote to this constitution runs*: "A National Medical Service should include the establishment of a medical service available to all members of the community, and providing every necessary form of medical, surgical, obstetrical, dental, and preventive treatment, co-ordinated as one service under the Ministry of Health. This would entail the provision of all necessary institutional treatment, consultant and specialist services, together with all known means for the prevention, diagnosis, and treatment of disease. The attainment of these objects will involve *the formulation* of a scheme or schemes by which the existing national health services and other State, municipal, and public services can be transformed, extended, and evolved into a comprehensive National Medical Service."

A THREE months' course of lectures and demonstrations in clinical practice and in hospital administration for the diploma in public health commenced on April 9th at the North-Eastern Hospital, St. Ann's Road, Tottenham, N.15. They will be continued on Mondays and Wednesdays, at 4.45 p.m., and alternate Saturdays at 11 a.m. The fee for the course, which complies with the revised regulations of the General Medical Council, is £4 4s. A course under the old regulations may be taken for £3 3s.

OWING to the Easter vacation no special courses have been arranged to be held under the auspices of the Fellowship of Medicine until April 28th, on which date three courses begin. These are an intensive clinical course in ear, nose, and throat diseases at the Central London Throat, Nose, and Ear Hospital, for four weeks; a four weeks' comprehensive course continuing until May 30th at the *Maudsley Hospital*, consisting of a series of lectures and demonstrations dealing with psychological medicine from various aspects; and an afternoon course lasting for two weeks at the Infants Hospital, under the direction of Dr. Eric Pritchard, especially suitable for those interested in infant welfare work. Several courses will take place in May, the subjects including: dermatology, at St. John's Hospital; ante-natal treatment, at the Royal Free Hospital; diseases of the chest, at the Victoria Park Hospital; diseases of children, at the Hospital for Sick Children; and medicine, surgery, and the specialties, at the Queen Mary's Hospital. From May 13th to July 4th there will be a course for the M.R.C.P. examination. Detailed syllabuses of all courses can be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE tenth of the series of congresses known as the Journées Médicales de Bruxelles will be held from June 28th to July 2nd, under the presidency of Professor Jules Bordet, and in connexion with the celebration of the centenary of Belgian independence. In addition to the usual meetings and receptions in Brussels, a visit will be paid to Liège. The French and Belgian railways will allow a reduction of 35 per cent. on the ordinary charges. Further information may be obtained from the general secretary, Dr. R. Beckers, 62, rue Froissart, Brussels.

THE eighth International Congress of Dermatology and Syphilis will be held at Copenhagen from August 5th to 9th, when the subjects for discussion will be the etiology and pathogenesis of eczema, immunity, reinfection, and superinfection in syphilis, and cutaneous tuberculosis and its treatment. Further information can be obtained from the general secretary, Dr. Svend Lomholt, Copenhagen.

THE annual congress of the German Society for Investigation of the Circulation will be held at Dresden on June 11th and 12th. Further information can be obtained from Professor Bruno Kisch, Köln-Lindenthal, Lindenberg.

THE report of the Joint Tuberculosis Council for 1928 and 1929 gives an outline of the activities of that body since the issue of the last report in January, 1928. Special mention is made of a memorandum on disinfection in tuberculosis circulated by the Council, and the statistical research on the fate of young children in tuberculous households, which was undertaken by Dr. Lissant Cox and the Lancashire group of tuberculosis officers. A recent memorandum by the Council on the subject of notification was circulated at the beginning of this year, and was mentioned in our columns on March 1st (p. 427). The report also refers to the steps taken by the Council to improve the tuberculosis service, to promote post-graduate study, and to ascertain the position with regard to the employment of tuberculous patients. The Joint Council includes representatives of medical organizations and Government departments; the British Medical Association is represented by Dr. C. O. Hawthorne and Dr. Arnold Lyndon.

A NEW catalogue of medical books has been issued by the Oxford University Press, including details of nearly 400 current works on medicine, surgery, and allied subjects, duly classified. We are informed that specimen copies of all these books may be inspected in the library at the London office of the Press, Amen House, Warwick Square, E.C.4.

THE Walton Hospital Training School for Nurses, Liverpool, has issued an illustrated booklet giving particulars of the training it provides for probationers and certificated nurses who are studying for the final examinations of the General Nursing Council and of the Central Midwives Board. Courses are also available for male nurses. The hospital, which is subject to inspection by the Ministry of Health and the General Nursing Council, has about 1,650 beds, and over 13,000 patients pass through the wards every year.

AT a meeting of the Chelsea Clinical Society, at the Hotel Rembrandt, Thurloe Place, S.W., on April 15th, at 8.30 p.m. Dr. R. A. Young and Mr. Philip Franklin will open a discussion on "Coughing." The meeting will be preceded by dinner at 7.30.

THE annual dinner of the Medical Superintendents' Society took place at the Holborn Restaurant on March 28th, with the president, Dr. E. W. G. Masterman, in the chair. Dr. Daly, in proposing the toast of "The Society," recalled some of the past history of the society, which was formed in 1887. Dr. Masterman, in reply, outlined the society's activities in the past, and pointed out that its name had been changed from Infirmary Medical Superintendents' Society so as to enlarge its membership, which now embraced medical superintendents of all public hospitals and voluntary hospitals, and whole-time medical officers in responsible charge of patients in public hospitals or institutions for the sick. Dr. Barrie Lambert, in reply to the toast of "The Guests," emphasized the enormous work the London County Council had undertaken, and showed the need for co-operation between the London County Council and the medical superintendents. Dr. J. J. Buchan, as a medical officer of health, stressed the need for co-operation between the curative and the preventive side of medicine.

AS an extension of the work of the St. John Ambulance Association, the first of three special rail coaches, designed to promote first-aid instruction among the 100,000 employees of the Canadian National Railways Company, has just been brought into use. The cars, which are miniature hospitals, including the latest emergency equipment and lecture theatres for first-aid demonstrations, will be used primarily in the more remote parts of Canada where the opportunities for the study of first aid under competent instructors are limited. Employees of the railway are encouraged to attend lectures on first aid in working hours, a corps of experts being retained for demonstration purposes. A special Canadian National Railway Council of the St. John Ambulance Association was established some years ago, and as a result of its activity 35,000 employees have obtained certificates of proficiency in first aid.

THE KING has granted authority to Dr. B. Spearman, Deputy Director of Sanitary Services, Zanzibar, to wear the Insignia of Class III of the Order of the Brilliant Star, conferred upon him by the Sultan of Zanzibar in recognition of valuable services rendered.

THE Union Castle Steamship Company has issued a series of folders giving particulars of a special summer tour to South Africa at reduced return fares, fortnightly holiday cruises from London to Antwerp, Rotterdam, Hamburg, and back, and weekly sailings to Madeira and the Canary Islands. Further information may be had from the Union Castle Mail Steamship Company, Ltd., 3, Fenchurch Street, London, E.C.3.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

REMOVAL OF TATTOO MARK.

"E. R. T." asks for suggestions for the removal of a large tattoo mark which has been present for some twenty years on the right arm of a woman, aged 35, and is causing her much worry.

POST-ENCEPHALITIS: RE-EDUCATION.

"G. W." would be glad to learn if there is any institution or any individual who undertakes the re-education of a post-encephalitic condition where the disease itself is arrested. There is partial paresis of the left humero-scapular region and lack of initiative. Parkinson's syndrome is obvious.

*** Since November, 1925, the Metropolitan Asylums Board has arranged for the after-care and treatment of post-encephalitis patients at the Northern Hospital, Winchmore Hill, London, N.21. Among other post-encephalitis units are Southmead Hospital, Bristol, Darenth Training Colony, Dartford, and Swinton Home, Manchester.

INCOME TAX.

Is an Honorarium Assessable?

"R. M." has given ambulance lectures to the employees of a colliery company for several years, and in each of the past three years the company has been paying him £10 10s. yearly as an acknowledgement for the services given in that way. Are these payments assessable as "R. M.'s" income.

*** In our opinion they are assessable. There are several cases dealing with honorariums payable in various circumstances—for example, the Easter offerings received by the clergy—and though we are not aware of a case quite similar to that put by "R. M.," the principle laid down seems to cover it—that is, that where the payment is made in respect of services rendered rather than as a personal benevolence, the recipient is assessable, and the payer can deduct the amount as a business expense. Further, if the colliery gave "R. M." something in kind instead of in cash the sale value in his hands, not necessarily the cost price to the company, would, on the same reasoning be assessable, in accordance with the principle laid down in Tennant *v.* Smith.

Income Transferred to Another Individual.

A. C. inquires as to the effect on taxation where "a sum of money is handed over by deed or paid periodically under a deed."

*** In such a case the annual amount handed over by virtue of a legally binding covenant to make the payment is income of the recipient and not of the payer. The latter, however, has to account to the Revenue for tax at the standard rate on the amount of the payment, but deducts the tax when effecting payment of the annuity. The recipient, therefore, suffers the tax at the standard rate by deduction, and can claim from the Inland Revenue Department the whole or such part of the tax as he may be entitled to claim. Suppose, for instance, that X undertakes by deed to pay his mother £25 a quarter for her life and assume that she has no other income. Then he pays out of his taxed income £25−£5 income tax = £20 sent the and she can claim repayment by the depart[illegible]e hospital quarter. This question of the legal transfer of income is, however, subject to various restrictions as regards its effect on taxation, particularly in the case of voluntary transfers for the benefit of a child of the transferor. If "A. C." has any particular set of facts in mind, perhaps he will state them in detail.

Assessments for Back Years.

"J. D." states that the income tax authorities say that he has not paid enough tax in previous years, and inquires how far back they are entitled to go; he also asks for reference to "a good book on income tax."

*** The right to assess profits which are discovered to have escaped assessment extends to the six years prior to the financial year current when such assessments are made. Of course, in a case where the inadequacy of the original payments of tax is due to wilful neglect or gross carelessness, the taxpayer concerned may prefer to make restitution for a longer period than six years rather than face proceedings for the recovery of the statutory penalties applicable to those six years. The standard books on income tax are expensive, and, for the most part, would be of no interest to a medical practitioner. Messrs. Nelson published an inexpensive income tax guide, which was as good as anything we have seen at the price, but if the tax involved is substantial "J. D." would probably find it best to employ an accountant familiar with income tax law and practice.

LETTERS, NOTES, ETC.

SUN AND AIR BATHING.

DR. REGINALD HODDER (Penge, S.E.) writes: The discussion at the recent meeting of the Section of Balneology and Climatology of the Royal Society of Medicine on the influence of sunlight and climate on health, brought out the important distinction between bathing in hot sunshine and active sun and air bathing. The beach loungers who, according to Dr. McClure, come home with deeply pigmented skins, *and* bronchitis, are victims of failure to appreciate this distinction. I agree with Dr. Buckley that movement of air is as important in the open as it is indoors. We hear a great deal about "sun bathing facilities" provided at this or that resort for the coming summer; in practice this means nothing more than that people will be permitted to loll around in blue-black bathing costumes absorbing potentially harmful heat rays. Moving air and ultra-violet light are essential to sun bathing, and that means that sun bathers must be practically *naked*. The *larger seaside corporations* can hardly be expected to tolerate nakedness, though a professional colleague tells me he bathed twenty years ago in Sweden with hundreds of respectable people of both sexes, all naked. *What we must* do, however, is to pass on to the public the *knowledge* we have about how ultra-violet radiations act through the skin, and ask public authorities to provide more facilities for persons who wish to practise sun and air bathing, and the public to adopt a more tolerant attitude towards nakedness in others. The Sun Bathing Society at Upper Norwood is an admirable example of what can be done; about sixty members exercise in the grounds at Sun Lodge wearing shorts or slips, the women supporting their breasts with brassieres. Air and light can reach the skin when such abbreviated costumes are worn.

CONTROL OF CONCEPTION.

DR. BINNIE DUNLOP (London, S.W.7) writes: Are you right in saying that the medical problem involved in birth control is quite separate from the economic one? One of your three medical questions is: "Can it be truly said *of any such measures* [of controlling conception] that *they produce no harmful effects?*" Well, the economic difficulty is such that the control of married people would not be influenced if even the least measures was proved to be slightly harmful. They would only be influenced if the effects were definitely *more harmful* than those of the alternatives to contraception. The reliable question is the most *important one*, and I hope that the safe ring method (*British Medical Journal*, January 18th, p. 1[illegible] which seems absolutely certain, will also *continue* to prove harmless in practically all cases.

INJECTION TREATMENT OF HYDROCELE: CORRIGENDA.

WITH reference to his article on the injection treatment of hydrocele (*Journal*, April 5th, p. 649), Dr. St. George R. Delisle (Ilfracombe) writes that, owing to a typing error, the word "phenol" was substituted for "formol" in the *translations* of the French articles quoted by him. *In lines* 5 *and* 8 of the first column, and in line 5 *from the foot* of the second column, for "*carbolic* acid" read "formaldehyde."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and *of* vacant resident *and* other appointments at hospitals elected [illegible] be found at pages 52, 54, 55, 56, 57, 60, 61, *and* 62 of Thomas[illegible]ertisement columns, and advertisements *as to* partnerships, locumtenancies, and assistantships at pages 58 *and* 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *119*.

T. S. [illegible]

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

350. Paratyphoid C Infection in British Guiana.

G. GIGLIOLI (*Trans. Roy. Soc. Trop. Med. and Hyg.*, November, 1929, p. 235) records observations on 92 cases of paratyphoid C infection admitted to the Demerara Bauxite Company Hospital at Mackenzie, British Guiana, between 1923 and 1928; 61 patients were males and 31 females. The ages ranged from under 1 year to 60 years, but most of the patients (45) were between 16 and 25. The race distribution was as follows: negroes 57, East Indians 4, aboriginal Indians 6, Portuguese 1, and mixed races 24. No particular relationship was observed between the rainfall and average mean temperature and the number of cases observed month by month from 1923 to June, 1928, except that there was a marked decline in the incidence of the disease during the first half of the drought years 1924 and 1926. Cases occurred throughout the year, but there was a decided increase during the winter months from November to May. Water, milk, food, and flies could be excluded as causes of spread of the infection, and the most likely means of distribution of the disease were carriers in the form of abortive cases, slight ambulatory infections simulating malaria, and convalescent patients. Urine was probably the most dangerous means of spreading the disease, not only on account of the large number of bacilli it contained, but also in consequence of the very insanitary habits of the population, who took no precautions as regards the disposal of urine. There appeared to be a close relationship between the incidence and distribution of paratyphoid C and malaria fever. Of the 92 patients, 32 died, a mortality of 38 per cent. These figures, however, do not indicate the actual mortality rate of the disease, since the great mass of the abortive, slight, and mild protracted cases escape observation.

351. Incidence of Tuberculosis in a Country District.

H. THORBORG and M. HOLM (*Ugeskrift for Laeger*, February 13th, 1930, p. 153) have performed Pirquet tests on all the patients admitted to a provincial Danish general hospital serving an area in which there were no large towns. Altogether 1,587 patients admitted in the period 1925–27 were thus examined, the tuberculin used being Koch's old tuberculin undiluted. As the object of this investigation was to determine the degree of tuberculous infection of the native population, the patients were classed in two main groups. In the first group the patients had been born in the neighbourhood and had lived there ever since. In the second group the patients had either not been born in the neighbourhood or had settled outside it for a shorter or longer period. Most of the patients in both groups were between the ages of 15 and 30. It was found that the frequency of positive reactions was considerably higher in the first than in the second group. For example, in the age period 15 to 24 only 33.2 per cent. of the 328 patients examined in the first group were Pirquet-positive, whereas in the second group in the same age period there were 90 positive reactions to 47 negative reactions—that is, 65.7 per cent. positive reactions. The difference was even more marked in the youngest age period (3 to 14 years), only 23.9 per cent. of the reactions being positive in the first group, as compared with 76.3 per cent. in the second group.

352. The Accessory Auricular Contraction in Stokes-Adams Syndrome.

E. GÉRAUDEL (*Arch. des Mal. du Cœur*, January, 1930, p. 18) refers to previous publications in which he has shown that the right auricle consists of an uppermost sinus or vestibular region, and a part which is of atrial origin and made up of superior and inferior diverticula. Two paths spring from the vestibular region, the uppermost supplying the superior atrial diverticulum and sending a branch to the inferior diverticulum, while the lower branch divides, supplying the inferior diverticulum and the ventricles; this latter division is the "bundle of His." If conduction in this bundle fails the patient's electro-cardiogram shows the usual curve of complete auriculo-ventricular dissociation; if the interruption in the conducting tract occurs higher up in the sino-ventricular path, before the separation of the branch to the inferior atrial diverticulum, a deviation may be found in the electro-cardiogram representing the contraction of this structure. This element of the tracing usually takes the form of a V; it is superimposed upon the ventricular complex and is known as Pi. Block occurring high in the sino-ventricular path will constantly produce the Pi wave provided the path connecting the superior and inferior atrial diverticula is also blocked. If this blocking is not present Pi only appears intermittently. Géraudel has reviewed the electro-cardiograms of forty-nine patients with Stokes-Adams syndrome, and has found the deviation Pi in eleven of them; in these patients, therefore, heart-block was due to a lesion above the bundle of His and above the auriculo-ventricular node. The deviation Pi was characteristically diphasic, and, although generally V-shaped, it was sometimes of opposite sign. Owing to the variable form of the element Pi and its appearance among the deviations of the ventricular complex it was frequently difficult to identify, and might be mistaken for a deformed ventricular complex.

353. Acute Influenzal Polyneuritis.

G. DALLA TORRE and A. CHINAGLIA (*Il Policlinico, Sez. Med.*, January 1st, 1930, p. 9) record an illustrative case, and have collected four others from the literature, reported by Bonnet, Leyden, Weill and Regand, and Bury respectively. The present case was that of a man, aged 40, who was admitted to hospital with tetraplegia of sudden onset, high fever, and general asthenia. Death ensued after about a fortnight's illness. The necropsy showed splenization of the lower lobe of the left lung, and a normal macroscopic appearance of the brain, spinal cord, and peripheral nerves. Histological examination, however, revealed the typical appearances of well-marked parenchymatous neuritis in the sciatic, popliteal, median, and ulnar nerves, the findings being similar to those described by the other writers mentioned previously.

354. Period of Infectivity and Serum Prevention of Chicken-pox.

J. E. GORDON and F. M. MEADER (*Journ. Amer. Med. Assoc.*, December 18th, 1929, p. 2013), as the result of their own experience and a study of the literature, come to the following conclusions. In the prodromal stage chicken-pox is apparently infectious for only a short period, and probably not more than twenty-four hours before the appearance of the eruption. In accordance with the experience of F. H. Thomson, they found that infectivity is less than is generally supposed, does not necessarily coincide with the persistence of scabs, and probably closes within ten days. Convalescence serum furnishes a high degree of protection (15 out of 16 cases) if obtained within one month of the appearance of the eruption, the dose being 10 c.cm. of a pooled serum. Serum obtained two to four months after the eruption proved less reliable, and after five months conferred protection in only a third of the susceptible individuals.

Surgery.

355. Abduction Treatment of Fracture of Neck of Femur.

R. WHITMAN (*Journ. of Bone and Joint Surg.*, January 1930, p. 11) describes the abduction treatment of fracture of the neck of the femur as being in accordance with that of other fractures, because the natural mechanics of the hip-joint are utilized to correct deformity and to oppose displaced fragments. By this treatment the limb is abducted, the fragments being brought into a horizontal plane, and therefore end-to-end. When this movement approaches the normal limit, tension on the capsule enclosing both fragments must appose and fix them in normal relation, direct bony contact being supplemented by complete suppression of muscular action. The limb is fixed in an attitude of full abduction, extension, and slight inward rotation, to maintain the essentials of functional repair. The long plastic spica is the most comfortable and efficient means of support, and permits the alteration of posture. Adequate protection and after-care are of great importance. It is contended that this new method of treatment is more satisfactory than older and more conventional methods. Comparative statistics are cited showing that among 169 cases of transcervical fractures treated by other methods the death rate was 12 per cent., and good results only occurred in 11.5 per cent., while among 176 cases of this type of fracture treated by the abduction method the death rate was 6 per cent. and bony union was attained in 67.5 per cent. of cases. It is therefore seen that the strict application of surgical principles is practicable in most instances, that the danger is slight, and that union of the transcervical fracture may be obtained in the larger proportion of cases.

356. Thyroid Metastases in Bone.

W. K. CONNELL (*Brit. Journ. of Surg.*, January, 1930, p. 523) states that the commonest situation for tumours in or on bone, containing thyroid tissue, is the skull, with the sternum, vertebrae, ribs, humerus, femur, pelvis, and clavicle as possible but less frequent sites. Thyroid metastases usually appear first in the vicinity of the cranial sutures or of the epiphyses of the long bones, and may be encapsuled or diffuse, endosteal or periosteal, and sometimes osteoplastic. Some are pale and almost bloodless, while others are intensely vascular with vigorous pulsation. The structure of thyroid metastases may be that of a carcinoma, an adenocarcinoma, a "foetal adenoma," a simple parenchymatous or colloid goitre, normal thyroid gland tissues, or a combination of two or more of these. Growth is usually slow, and a thyroid osseous metastasis has been known to be present for twenty years. It is considered that all cases are probably dependent on the presence of a thyroid carcinoma which is so slow and insidious as to be overlooked; and it appears that the type of thyroid carcinoma which produces bone deposits is of relatively low virulence. When the metastasis is single and the risk not excessive, treatment consists in excision of the metastasis followed by thyroidectomy. All tumours of the thyroid should be regarded as potentially malignant. Two cases are quoted occurring in African women between the ages of 45 and 50, but treatment or much study of these cases was not possible as the patients did not remain in hospital.

357. Duodenal Ulcer in a Newborn Child.

I. S. SCHWARTZ (*Zentralbl. f. Chir.*, February 1st, 1930, p. 270) describes the clinical aspects and treatment of a fatal case of perforating duodenal ulcer in an infant two days after birth, and discusses the pathology of the condition. The only symptom is sudden uncontrollable haemorrhagic diarrhoea, which is sometimes accompanied by haematemesis, and causes a severe and fatal anaemia. Operative treatment is not advisable, but good results have been obtained by combating the anaemia by transfusion. The condition is attributed to some infection, or to a thrombus in the umbilical vein with subsequent embolism into the vessels of the duodenum and stomach; retrograde emboli may also pass from the umbilical vein into branches of the portal vein. In the case here reported the child had pemphigus neonatorum simplex; the Wassermann reaction was negative. The initial attack was treated by intramuscular gelatin, and 2 per cent. calcium chlorate was given by the mouth; the haemorrhage was arrested for forty-eight hours, but then recommenced, and 10 c.cm. of the mother's blood was transfused without result, the child soon dying from extreme anaemia.

358. Aneurysmal Varices of the Saphenous Vein.

N. C. ORTIZ and J. A. SALABER (*Rev. Sud-Américaine de Méd. et de Chir.*, February, 1930, p. 122) state that 55 per cent. of all venous aneurysms are those of the saphenous vein, and that their diagnosis is often difficult. Anatomically these dilatations can be divided into cylindroids and ampullas; the first are characterized by their uniform extension through the whole wall of part of the vein, while the second involve only a limited portion of the venous wall. The upper part of the vein is the most frequent site of this affection, the next most frequent being at the level of the knee; multiple dilatations occur more rarely. Etiologically, saphenous varices may be congenital or acquired. The first variety is due to a constitutional weakness in the vessel wall, and varices here coexist with others elsewhere. The acquired type is more frequent in adult males, and occupation does not appear to be a predisposing factor in their causation. Certain determining causes are inflammation (endophlebitis) and injuries of the vessel wall or of the nerves which control its nutrition. Clinically, these aneurysms may be divided into those with a free circulation, uncomplicated, and reducible; and those without free circulation, complicated, and irreducible. The former group presents as a tumour in the middle and internal part of Scarpa's triangle. The tumour is of various sizes, of bluish colour (an important sign in thin subjects), and of soft and fluctuating consistency; it is not painful and not adherent to the skin or subjacent tissues. On coughing a thrill can be felt over the tumour. Functionally, this affection causes difficulty in flexing the thigh and, in cases of large swellings, neuralgia of the internal saphenous nerve occurs. In irreducible aneurysms symptoms of phlebitis occur in addition to those mentioned. The tumour enlarges and becomes painful, hard, and irregular. The pain may radiate along the whole vein and even the whole limb. Malleolar oedema is also present. If the phlebitis extends to the pelvic veins, symptoms of general infection and abdominal troubles (vomiting, constipation, and meteorism) appear. This condition evolves slowly, and is often discovered accidentally or after some injury. Complications are phlebitis, thrombus formation, and suppuration. Saphenous varices must be differentiated from crural hernia, crural cystocele, arterio-venous aneurysms, lymphatic varices, abscesses with double sac, lipomas, and particularly from strangulated hernia. The treatment is essentially surgical, and palliative treatment (the wearing of an elastic bandage) is indicated only in those cases, such as advanced age, in which operation is contraindicated. In infected cases operation must not be undertaken until all infection has subsided.

Therapeutics.

359. Thallium Acetate in Ringworm of the Scalp.

G. H. PERCIVAL (*Brit. Journ. of Derm. and Syph.*, February, 1930, p. 59) describes a series of 50 cases of ringworm of the scalp which were treated with thallium. A single dose of 8.5 mg. thallium acetate per kilo of body weight was given, and 10 per cent. sulphur ointment was applied daily; after a good regrowth of hair had occurred the local treatment was suspended for three weeks, and the scalp was re-examined for signs of disease. Complete epilation occurred in every case in seventeen to twenty-two days; 96 per cent. of cases were definitely cured, the average duration of treatment being 107 days, as compared with 135 days in the case of 50 successful *x*-ray cases treated in Edinburgh during 1924. Mild toxic symptoms (muscular "pseudo-rheumatic" pains in the legs, lethargy, and slight headache) appeared in 44 per cent. of cases between the third and twenty-eighth days, and lasted two to nineteen days. The author stresses the importance of efficient local treatment during the period that the scalp is completely bald. Regrowth of hair occurred in twenty to thirty-four days in this series. The mode of action of the drug is still regarded as uncertain, and is not adequately explained by any endocrine or vasomotor influence. It is noteworthy that growth power persists in the hair bulbs for ten or eleven days after the ingestion of thallium, and subsequently undergoes temporary inhibition. If thallium has a local action, it is probable that it, like the *x* rays, exerts an inhibitory action on the more primitive and actively growing cells of the follicle and bulb.

360. Contraindications to Gold Salt Therapy.

BERNARD has recorded the beneficial results obtained in diabetes associated with pulmonary tuberculosis by the simultaneous employment of a dietetic and insulin therapy with artificial pneumothorax, and has called attention to the lack of efficacy and even the injurious action of gold salts in certain cases of this condition. M. VILLARET, L. JUSTIN-BESANÇON, and R. CACHERA (*Presse Méd.*, February 12th, 1930, p. 218) report such a case, doing so especially because they were the first French authorities to recommend this treatment in pulmonary tuberculosis. The association of pneumothorax and insulin had effected a considerable improvement in their patient, and for three years the advance of the tuberculous process had been checked and the diabetes stabilized. A first series of injections of the double thiosulphate of gold and sodium caused a very marked recrudescence of the lung condition, with fever, emaciation, and reappearance of bacilli in the sputum, even though the antidiabetic treatment was continued. A second series of injections of the same salt, with a diabetic treatment calculated on the patient's tolerance for carbohydrates, caused a still more serious recrudescence of the pulmonary disease with infiltration of the lung that had been free till then. This extension of the tuberculous process, in its turn, brought about an aggravation of the diabetes. The authors agree with Bernard as to the ill effects of gold salts in tuberculous diabetics.

361. Liver Treatment of Anaemia.

JANET M. VAUGHAN (*Quart. Journ. of Med.*, January, 1930, p. 213) reviews the present position of the liver treatment of anaemias, which are considered under four groups: (1) pernicious anaemia, (2) the anaemia of sprue and pregnancy, (3) haemorrhagic anaemia, and (4) anaemias of unknown origin, including leukaemia and cancer. For the groups (1) and (2), characterized by megaloblastic hyperplasia of the bone marrow, the administration of liver or liver extract is a certain remedy, though its action is seriously inhibited by the presence of sepsis. For some cases of group (3) liver treatment has a definite value; the other forms of anaemia in group (4) are unaffected by the treatment. The action of liver depends on at least two hepatic factors. The action of liver depends on at least two hepatic factors, one or the inorganic salt contents and a complex polypeptide, one or both of which may be effective in varying conditions. These factors act either as inducers or as inhibitors of megaloblast

formation. According to one view, liver provides a substance absent in pernicious anaemia, which is necessary for the maturation of megaloblasts, the anaemia being the result of a deficient production rather than a massive destruction of red cells. In patients under liver treatment for pernicious anaemia a sudden improvement of the mental outlook and a rapid gain in weight are as important signs of response to the remedy as a rise in the reticulocyte count.

362. Injections of Trypaflavine in Meningococcal Septicaemia.

A. BÖTZEI (*Med. Klin.*, January 24th, 1930, p. 127) records two cases of the successful use of trypaflavine in a woman aged 30 and a youth aged 17, who presented the characteristic symptoms of protracted meningococcal septicaemia as described by Friedemann and Deicher in 1926—namely, an eruption resembling erythema multiforme, a temperature like that of tertian malaria, pain and swelling of the joints, and leucocytosis with a distinct shift to the left. As a general rule the disease lasts for several months, and though a spontaneous recovery may occur there is always the possibility of the supervention of meningitis. The author advises that trypaflavine, which was first introduced by Adler in 1922, should be injected intravenously in large doses for adults (0.6 to 0.75 gram). This treatment produces a rapid cure of the protracted form of meningococcal septicaemia, but is inefficient in the acute form in which the blood shows a massive infection with meningococci.

Anaesthetics.

363. Regional Anaesthesia in Urology.

C. M. JOHNSON (*Journ. Amer. Med. Assoc.*, December 21st, 1929, p. 1942) considers that regional anaesthesia is particularly suitable in urological surgery. In a series of over 300 cases three types of anaesthesia were employed: simple caudal block; caudal anaesthesia, together with transsacral block by injection of the sacral canal and the first, second, and third sacral foramina; and spinal anaesthesia. The relaxation of the vesical sphincters so obtained may confuse the cystoscopist in studying accurately the posterior urethra and bladder neck; this constitutes a disadvantage to the method. Its advantages, however, are so numerous that the author considers that it excels all others, affording as it does perfect anaesthesia lasting an hour and a half for any cystoscopic work, the anaesthesia being capable of repetition at frequent intervals if needed. The patient is able to co-operate throughout, and there is no suppression of renal function, no serious reaction, and no unpleasant sequels. In abdominal surgery of the lower genito-urinary tract spinal anaesthesia as an adjunct to gas and oxygen is said to be especially valuable. The author reserves it for operations on the lower ureters and lower abdomen, for nephrectomies in poor risks, and for cystotomy or suprapubic prostatectomy. He believes that it will become increasingly used as both the profession and the public gain confidence in it.

364. Dangers of Trigeminal Anaesthesia.

A. LINDEMANN (*Schmerz, Narkose-Anaesthesie*, January 15th, 1930, p. 363) illustrates the frequency of sequels in trigeminal anaesthesia by the fact that 28 such cases occurred in 1927, there were 23 in 1928, and 19 in the first half of 1929 in the West German Jaw Clinic at Düsseldorf. In almost all these cases intraoral or regional anaesthesia had been induced; it was followed in several instances by severe general infection, which in four cases ended fatally, while in another twelve cases serious and mostly irreparable damage to the soft and bony parts of the jaw developed. Lindemann urges prophylaxis in respect of careful preparation of the solution to be injected, with preliminary attention to the mouth, especially at the site of injection, which is best treated by a solution of iodine in alcohol. The injection should be given slowly, and massage of the injected part should be avoided. After the injection the patient should not speak or take any food for some hours in order to prevent any infective material gaining entrance through the site of injection.

365. Nitrous Oxide-Oxygen Anaesthesia in Tonsillectomy.

J. H. EVANS (*Anesthesia and Analgesia*, January-February, 1930, p. 14) believes that the technique of performing tonsillectomies under nitrous oxide-oxygen merits developing if only for those cases where ether is contraindicated. He records a brief summary of observations of approximately 6,000 tonsillectomies under this form of anaesthesia, a series in which there were no deaths and no lung abscesses. Evans agrees that the appetite usually returns more quickly and there is less nausea and vomiting when no ether is used, but he emphasizes the point that the anaesthetist should be conversant with this method of anaesthesia, since it is dangerous in the hands of a novice. The apparatus should be capable of delivering a large volume of the gases to meet the requirements of mouth-breathers, and it should be so constructed that pure oxygen can be forced into the lungs if necessary. This form of anaesthesia is the most pleasant for the patient, both for induction and for recovery; it is also entirely free from any risk of explosion. The anaesthesia is not likely to be so deep as to permit of the inhalation of infected material: in this, as with other procedures, the anaesthesia should not be pushed to the extent of abolishing the cough reflex. A disadvantage which has been encountered is the difficulty of knowing if the patient is too lightly or too deeply anaesthetized. The colour sign, while important, is not always reliable; Evans believes in maintaining at least a fairly pink colour. Of greater importance are the muscular signs, due to anoxaemia: these consist of twitchings and jerkings, and, in very young children, a jactitation of all the muscles of the body. In the latter cases it is usually better to add a trace of ether and give a higher percentage of oxygen. The pre-operative administration of morphine or some other narcotic is said to be more helpful than with any other form of anaesthetic. An important pre-operative measure is the winning of the patient's confidence. Adults, and occasionally children, may be given aspirin, to be dissolved on the tongue every four hours for the first day or two to lessen the pain of swallowing. Soft food may be allowed a few hours after operation if the patient desires it.

Obstetrics and Gynaecology.

366. Persistent Hiccup during Pregnancy.

SUZOR (*Bull. Soc. d'Obstét. et de Gynécol.*, December, 1929, p. 690) reports a case of persistent hiccup during pregnancy. The patient, aged 25, consulted the author during her second pregnancy, one month after the cessation of menses; she had then had incessant hiccup for three days. She had suffered from influenza with pulmonary complications in the previous year, and her first pregnancy had been complicated by persistent hiccup and vomiting which began one month after conception. Every possible therapeutic measure had been employed in an endeavour to stop the hiccup, but without success; the patient had refused to allow the pregnancy to be terminated, and the hiccup and vomiting persisted until the somewhat premature delivery. When she presented herself for treatment during her second pregnancy she appeared to be in good general condition, but was having hiccups at the rate of one spasmodic contraction a second. The uterus was enlarged and soft, and the abdomen was meteorized by aerophagia. The pulse was 72 and the tension normal, as were the reflexes. Compression of the phrenic nerve had no effect on the contractions. A subcutaneous injection of 1 cg. of spasmalgine diminished the frequency to 44 hiccups to the minute, but the patient obtained no sleep during the night and the next day an intravenous injection of soluble gardenol was without effect. She was watched throughout the day and night and had between 50,000 and 80,000 spasmodic contractions in the twenty-four hours. There was a manifest increase in frequency each time the patient was disturbed on the occasion of an examination. The contractions seemed to be more intense in the superior respiratory muscles. The author concluded that the hiccup was of nervous origin, and informed the patient that pregnancy would be terminated. peri-uterine anaesthesia was induced without effect. The following day the uterus was curetted: the hiccup did not cease immediately but progressively, the intensity of the contractions diminishing with the frequency.

367. The Course of Pelvic Infections.

H. SCHMITT (*New England Journ. of Med.*, December 5th, 1929, p. 1149) states that in one series of 916 consecutive gynaecological cases 28.78 per cent. were pelvic infections, while in another series of 903, 20.54 per cent. were of this nature. Approximately 75 per cent. of these infections were gonorrhoeal, 20 per cent. pyogenic or septic, and 5 per cent. tuberculous. The author believes that pelvic infections are self-limited processes: he finds that if they are treated conservatively about 65 per cent. end in complete cure, with restitution of the normal physiological and anatomical functions. In about 20 per cent. the patients become free from symptoms and regain their capacity for work and enjoyment of life, though permanent pathological processes remain. Sterility is usually present in these cases. The remaining 15 per cent. of the patients are chronic invalids who have to undergo radical surgical treatment before health can be restored. In such cases, he remarks, while proceeding with the treatment an attempt should be made to remove

the infection and at the same time to conserve ovulation, menstruation, and fruitfulness. If the tubal lumen is found by the air inflation test to be closed, and the site of obstruction can be determined by hystero-salpingography, plastic operations are indicated. If both tubes have to be removed *the insertion of a healthy ovary into the uterine cavity may* be considered.

368. Relief Measures during Labour.

H. W. SCHOENECK (*Amer. Journ. of Surg.*, December, 1929, p. 778) reviews 435 cases of labour treated in hospital, of which the mortality rate was 0.68 per cent. It was found that normal labour was the safest means of delivery; the maternal morbidity, which was determined by a rise in temperature to 100° F. or more for a period of at least two days between the second and fourteenth day, being less in spontaneous labour than in delivery by prophylactic forceps or version; lacerations of the birth canal were also lessened in number and degree. The maternal and foetal mortalities in this series were *nil*. Prophylactic or low forceps application gave the next lowest foetal mortality and maternal morbidity, while prophylactic version resulted in the highest proportion of these. The author remarks that the Kronig method of administering morphine and scopolamine affords *relief in both stages of labour. The amnesia obtained avoids* the harmful effects of the mental and physical suffering to a greater extent than does prophylactic version or prophylactic forceps, though if the latter supplements the use of morphine and scopolamine the benefits from these drugs are enhanced. A state of amnesia is to be aimed at, and not analgesia, the interval between the first dose and delivery being at least four hours. It was found that the necessity for instrumental delivery was frequent owing to the inability of the patient to use her abdominal muscles at the expulsive stage. A further 200 cases were delivered subsequently, Gwathmey's rectal anaesthesia, combined with morphine and scopolamine, being employed as a relief measure, and a solution of acriflavine, 5 per cent. in 50 per cent. alcohol and 10 per cent. acetone, being used as an antiseptic instead of iodine. Three ounces of this solution were instilled in the vagina at the onset of labour, and it was applied to the vulva, perineum, thighs, and lower abdomen at the time of delivery. *This treatment was* followed by a startling drop in the general morbidity rate to 1.8 per cent. The combination of instillation of ether, quinine, and oil with scopolamine and morphine was found to give a higher percentage of satisfactory results than the modified twilight sleep; for the relief of multiparae one dose of morphine sulphate 1/6 grain, scopolamine 1/150 grain, followed by rectal instillation, gave satisfactory analgesia and amnesia for two or more hours. Fractional doses of ether and oil were repeated in most cases until after delivery. It is contended that by these means the risk of puerperal fever is diminished and greater relief given during labour.

369. Ergotamine in Treatment of Uterine Haemorrhage.

C. COGGI (*Riv. d'Ostet. e Ginecol. Prat.*, January, 1930, p. 6) describes experimental studies showing that ergotamine exercises a stimulant action on the guinea-pig's uterus which is increasingly effective during the course of pregnancy and is only slightly diminished during the puerperium. He reports administration of ergotamine tartrate solution, in medium doses, by the mouth or intramuscularly, in 2 cases *of post-partum uterine inertia*, 44 *cases of uterine inertia* following; abortion, 37 cases of post-partum uterine subinvolution, and 11 cases of uterine subinvolution following abortion (spontaneous or operative). All the patients except one responded well and quickly to the treatment.

Pathology.

370. Effects of Splenic Opotherapy on the Blood.

J. MOUZON (*Presse Méd.*, February 12th, 1930, p. 219) reviews the recent work on the therapeutic employment of splenic extracts. Bayle has shown that the absolutely constant sign of their beneficial effect is an increase in the erythrocytes, often by as much as a million, and also in the haemoglobin; this is followed by a leucocytosis with a predominance of lymphocytes and eosinophils. These findings have been confirmed by many authorities *in all countries. This haematological* action of the extracts, which has been observed in both subjects and anaemic conditions, is very marked and persistent after intravenous injection, less after intramuscular injection, and very much less after oral ingestion. On the other hand, many authorities (notably Mayr and Meltzer) have found that the administration of splenic extracts causes a decrease of an eosinophilia. These results have been observed both in animal experiments and in the treatment of polycythaemia and in eosinophilic conditions, especially in the dermatoses which often accompany them. Great benefits have followed the use of the extracts in such conditions as erythrodermia, chronic eczema, prurigo, and pemphigus, these skin diseases being precisely those usually attributed to allergic causes. *With regard to this* double haematopoietic and haemolytic action, Verzar has shown that dry or aqueous splenic extracts contain two substances of opposite properties, which act in different conditions, and Zih has demonstrated that small doses have a haematopoietic action, while large ones are haemolytic. The latter worker has also noted that animals with a high cell count are more sensitive to the haemolytic effects and those with low counts to the haematopoietic effects, equal doses being given to each series. Mouzon suggests that polycythaemia may be due to the survival of too old cells, and that the splenic extract supplies to the organism a factor which enables it to destroy these useless cells; in anaemic states, however, a factor may be concerned which facilitates the formation of red cells and the increase of their haemoglobin content. He adds that the very specialized structure of the spleen is without doubt an important agent in its physiological functions, and that nothing indicates the presence of an internal secretion. Many other properties have been attributed to splenic extracts; among these are their action on the blood platelets, on infectious leucocytosis, and on cardiac tonus.

371. Tubercle Bacilli in Laryngeal Smear Preparations.

H. BEHMANN (*Münch. med. Woch.*, January 10th, 1930, p. 62) finds that tubercle bacilli can often be demonstrated in a smear from the larynx in cases of pulmonary tuberculosis in which sputum is otherwise unobtainable, or there is some suspicion of malingering or intentional mixing of specimens. A positive result can also be obtained sometimes by this means more quickly than from specimens of sputum procured in the usual way; cases of tuberculosis of the larynx are excluded from this discussion. The following technique is adopted. A probe carrying a wool swab is passed over the posterior surface of the epiglottis into the larynx and the patient is asked to cough; the very small quantities of sputum *thus obtained* adhering to different parts of the swab are spread as close together as possible on a microscope slide, and the stained material is very carefully examined for acid-fast bacilli before *it is pronounced* negative. A similar manœuvre is also useful in obtaining sputum for examination from children in various respiratory conditions.

372. The Significance of Ketogenesis.

BASING his views on Knoop's theory of the β-oxidation of the fatty acids in the body, A. B. MACALLUM (*Canadian Med. Assoc. Journ.*, January, 1930, p. 3) believes that in each stage there is formed, first a β-hydroxy acid and then from the latter a β-oxy acid, eventually CO_2 and H_2O. In this progressive oxidation of a molecule of fat there must be a "pull" on the oxygen available to carry that oxidation to completion before the initial oxidation of other fat. Of all the β-hydroxy and β-oxy acids found in the metabolism of fat from its fatty acids, β-hydroxybutyric and β-oxybutyric are the only ones soluble in water and, therefore, diffusible from the cells engaged in metabolism. Even in normal subjects traces of these acids appear in the blood. The oxidation of β-oxybutyric acid requires a *comparatively* large quantity of oxygen, and, if it is incomplete, acetone is formed. The supply of oxygen to the metabolizing cells, constantly replenished from that in the blood, is limited to the maximum these cells are capable of receiving and utilizing from moment to moment. This supply is for the most part used in the oxidation of the sugar and the fat present. Since the sugar is much more easily and therefore more quickly oxidized, a considerable portion of the oxygen held by the oxidizing complex is so used, the rest being left for the oxidation of fat. If glucose is sufficiently plentiful there will be little or no oxygen for the oxidation of fat. The production of β-hydroxybutyric and β-oxybutyric acids will be small. But when the sugar is unoxidizable, as in the diabetic, or is wanting in the normal subject after more or less prolonged fasting, a relatively large quantity of oxygen is available for the oxidation of fat, relatively large quantities of β-hydroxybutyric and β-oxybutyric acids are formed, and their diffusion *pressure is so great that they* escape from the cells in more or less considerable quantities, passing into the blood and eventually into the urine. In severe diabetes the fat supply in, or very immediately accessible to, the metabolizing cells has been so reduced that even when all the oxygen supply is available for the oxidation of the fat—as, for example, during fasting—the β-hydroxybutyric and β-oxybutyric acids are formed in such moderate quantities that they are oxidized before they can diffuse out of the cells.

"OSTELIN" VITAMIN D

PREPARATIONS AND PRICES

OSTELIN LIQUID

Ostelin Liq.) Ostelin vitamin D suspended in glycerin.

Three minims equal in vitamin D potency one drachm of cod-liver oil. Tasteless, it may be given in water or milk, on sugar or in mixtures.

DOSE.

Children, 1-4 drops; Adults, 3-5 drops, t.d.s.p.c.

8 c.c. phials - - 2/6

OSTELIN TABLETS

(Tab. Ostelin Co.)

These tablets are a combination of calcium and Ostelin vitamin D Sugar-coated, equalling Ostelin Liq. m 3 and Calc. Glycerophos. gr. 2 Disintegrate readily.

DOSE.

Children, 1-3 daily; Adults, 1-3 thrice daily.

45 tablets - - - 2/6

OSTOMALT

(Ext. Malti c Ostelin Co.) Ostelin with Malt Extract and Orange Juice.

Containing vitamins A, B, C and D, together with calcium glycerophosphate. One teaspoonful contains the vitamin D equivalent of half-a-teaspoonful of cod-liver oil with orange juice, and 0.5% of Calc. Glycerophos.

DOSE.

Children, ½-1 teaspoonful; Adults, 1-3 teaspoonfuls.

1lb. & ½lb. jars 4/- & 2/6

OSTELIN EMULSION

(Emuls. Ostelin Co.)

A very palatable emulsion containing Ostelin vitamin D equal to 50% of cod-liver oil, and 0.5% Calc. Glycerophos.

DOSE.

Children, ½-1 teaspoonful; Adults, 1-3 teaspoonfuls.

In 8-oz. bottles - 2/6

ALSO

COLLOIDAL CALCIUM with Ostelin vitamin D Ampoules. For subcutaneous injection. 1 c.c. ampoules, 6 in a box - 5/-

OSTELIN with PARATHYROID TABLETS *(Tab. Ostelin c Parathyroid.)* Sugar-coated tablets = Ostelin Liq. m.3, Parathyroid Sicc. gr. 1/40th, Calc. Glycerophos. gr. 2. Bottles of 100 tablets - - 8/9

OSNOL Nasal spray. A solution of Ostelin vitamin D in neutral petroleum, for use in catarrhal conditions of the nose. 1 oz. bottles - 3/-

The above prices are subject to the usual professional discount. Any request for further information should be directed to

IMPORTANT REDUCTIONS
"VITA" GLASS PRICES

Now Definitely Established on a Permanent Basis

"Vita" Glass, in common with all new inventions, has passed through various stages of public confidence since it was introduced. At first it was considered an experimental product whose practical value had yet to be proved. The demand was small and of necessity prices were high. But gradually, as its success as a daily health measure became apparent, the demand grew and prices were lowered accordingly.

To-day "Vita" Glass can take its place as an economic necessity. It is the only British window glass that admits the ultra-violet rays, and it is recognised everywhere as a practical means of introducing health from daylight into the lives of those who live and work indoors. The demand is increasing steadily month by month and the time has come when prices can be definitely established on a permanent basis.

REDUCED PRICES

CLEAR SHEET "VITA" GLASS 1/-, 1/3 and 1/9 per square foot, according to size.

POLISHED PLATE "VITA" GLASS 1/6, 3/- or more per square foot, according to size.

CATHEDRAL (semi-transparent) "VITA" GLASS 1/- and 1/6 per square foot, according to size.

WIRED "VITA" GLASS (Georgian design) 2/6 per square foot.

HORTICULTURAL "VITA" GLASS for Poultry Houses, Greenhouses, Farmsheds, etc., 1/- per square foot.

For full particulars write to the "Vita" Glass Marketing Board, 9, Crown Glass Works, St. Helens, Lancashire.

"Vita" Glass is obtainable through local Glass Merchants, Plumbers, Glaziers or Builders. "Vita" is the registered Trade Mark of Pilkington Brothers Limited, St. Helens.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It corrects sounds from all ranges and angles.
5. It is entirely different, unexpicable and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope especially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

SOLID IODINE

A Remarkable advance in the presentation of H_2O_2

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.

Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.

A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 93, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'

SOLIDIFIED PEROXIDE OF HYDROGEN

in neat, handy glass tubes.

SULPHAQUA

LARGELY AND SUCCESSFULLY PRESCRIBED IN

Skin Diseases, Rheumatism, Gout, Neurasthenic : : Conditions in Arthritic Subjects, Etc. : :

And as a valuable addition to the Inunction TREATMENT OF SYPHILIS with Mercury.

Employed in BATH and TOILET BASIN.

Possesses powerful Antiseptic, Antiparasitic, and Antalgic properties. Relieves intense Itching and Pain, is WITHOUT OBJECTIONABLE ODOUR, and does not blacken the bath enamel. Recommended for the Skin and Hair. Especially useful in the treatment of Acne and Seborrhoea of the Scalp. Largely used in dermatological practice.

SULPHAQUA SOAP.

In Boxes of ½-doz. and 1-doz. BATH CHARGES, 2-doz. TOILET CHARGES, and ¼-doz. SOAP TABLETS.

Vapo-Cresolene Est. 1879

Sold by all Chemists

Write for descriptive Booklet No. 39B.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

MEDICAL SUPT., FELIX SAVY, M.B., Ch.B. *For particulars apply to the Secretary.*

NEURALGIA AND NEURITIS

Few diseases cause so much suffering as nerve pains, such as sciatica, trigeminal neuralgia, brachialgia, and intercostal neuralgia.

This group of diseases is rapidly and effectively treated at Pistany (Czechoslovakia) by volcanic mud—driven to the surface by hot sulphur springs. Statistics show that of 100 patients, only less than 5% do not respond to the treatment -30% are completely relieved and 65% are considerably improved.

Pistany RADIO-ACTIVE Mud Packs and Compresses are simply and easily applied. This treatment may be successfully combined with other physiotherapeutic methods.

Aden Settlement, ADEN, ARABIA.

The Executive Committee of the Aden Settlement invite applications for the post of MEDICAL OFFICER OF HEALTH. Applicants must possess a Diploma in Public Health or its equivalent, and preference will be given to holders of the Diploma in Tropical Medicine with Eastern experience. The salary will be Rs.800 per mensem (approximately £60 at the current rate of exchange), rising by annual increments of Rs.50 per mensem to Rs.1,000 per mensem, plus a car allowance of Rs.150 and a free unfurnished bungalow with water. The person appointed will be subject to the general control of the Executive Committee, but will work under the technical supervision of the Civil Administrative Medical Officer, Aden, who is a member of the Committee.

The appointment will be made on a two years' initial contract, subject to a probationary period of six months, with four months' leave on full pay on termination of initial contract, if re-engaged, or two months if not re-engaged. Free passage (first-class by British India Steamers or its equivalent) to and from Aden will be provided plus reasonable travelling expenses to port of embarkation.

Applications, with photograph (to be returned), stating age, nationality, and previous experience, with copies of testimonials (which will not be returned), should be sent without delay to the Chairman of the Executive Committee, Aden Settlement, Aden.

D. S. JOHNSTON (Major, R.E.),
Chairman, Aden Settlement.

Aden, March 14th, 1930.

Hong-Kong.

Vacancies at present exist for MEDICAL OFFICERS in Hong-Kong.

Salary. £600 per annum, rising by annual increments of £30 to £1,020 per annum, subject to deduction of 4 per cent. of salary as contribution to the Widows and Orphans Pension Scheme.

Qualifications. Applicants should be under 35 years of age. Preference will be given to candidates who have held Hospital appointments as House Physicians and House Surgeons.

Quarters. Partly furnished quarters, if available, are provided at a rental not exceeding 7 per cent. of salary; or an allowance is given in lieu.

Passages. Free passages are provided.

Terms of Appointment. The selected candidate will be engaged on a probationary agreement of three years, at the end of which period he will, if his services are satisfactory, and subject to his being certified medically fit, be placed on the permanent establishment.

Further particulars and forms of application may be obtained, on application in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Completed applications must reach the Private Secretary not later than May 3rd, 1930.

City of Georgetown, BRITISH GUIANA.

MEDICAL OFFICER OF HEALTH.

Applications are invited by the Mayor and Town Council of Georgetown for the appointment of a Medical Officer of Health of Georgetown, a city with a population of 55,000, and an area of approximately 2½ square miles.

Candidates must possess among other qualifications the Diploma of Public Health from a recognized Authority in the United Kingdom. They should state age, and also experience (if any) in the duties pertaining to a Medical Officer of Health.

The salary offered by the Council is £800 per annum, rising to £900 by annual increments of £25, and a travelling allowance of £100 per annum.

The appointment and dismissal of the Medical Officer of Health is subject to the concurrence of the Governor-in-Council of the Colony.

The successful candidate will be required to devote the whole of his time to the duties of his office and not to engage in private practice.

The appointment does not carry with it any pension rights, the granting of a pension or otherwise being by statute entirely in the discretion of the Council, who may award a pension for satisfactory long service.

The appointee will be entitled under the Council's leave Regulations to three months' vacation leave on full pay and three months on half pay for every completed three years' service.

The successful applicant will be required to pass a medical examination before assuming the duties of his office.

Applications, with copies of three testimonials, should be sent to the Director, London School of Hygiene and Tropical Medicine, Keppel St., London, W.C.1, not later than April 25th.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£50	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£50	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rate of pension are as follows:	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officer's embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in April to consider applications, and the selected candidates will be required to join a course of instruction on the 22nd April, 1930. Applications should be submitted as soon as possible.

British Medical Association.

APPOINTMENT OF ASSISTANT MEDICAL SECRETARY.

The Council of the British Medical Association is prepared to receive applications from registered Medical Practitioners for the appointment of an Assistant Medical Secretary. He will be required to work under the instructions of the Medical Secretary and to give his whole time to the duties of his office. If then considered suitable he will succeed to the post of Deputy Medical Secretary in October, 1932 (when the present Medical Secretary retires). Duties to commence on February 1st, 1931, and the appointment will be subject to six months' notice on either side.

Salary £1,000 per annum, subject to deduction for superannuation.

Applications, stating experience and age, with not more than three recent testimonials, should be sent to the Medical Secretary, British Medical Association, Tavistock Square, W.C.1, not later than by first post, May 12th, 1930.

Canvassing not allowed.

ALFRED COX, Medical Secretary.

St. Mary's Hospital, Institute of Pathology and Research.

Principal: SIR ALMROTH E. WRIGHT.

Applications are invited from qualified Medical Practitioners for a RESEARCH STUDENTSHIP. This will be tenable for six months, and may be renewed for a second period of six months.

The Institute comprises the following departments: Anatomy and Embryology, Physiology, Pathology, Chemical Pathology, Clinical Bacteriology, Systematic Bacteriology, and Immunology.

The student, who will receive an honorarium at the rate of £200 per annum, may elect to carry out his researches in any one of these departments, and would be required to work under the direction of the head of the department concerned.

Preference will be given to old St. Mary's Students.

For further particulars apply to the Secretary, Institute of Pathology and Research, St. Mary's Hospital, Paddington, W.2, to whom applications must be sent not later than April 28th.

Administrative County of London.

The LONDON COUNTY COUNCIL invites applications for the position of JUNIOR ASSISTANT MEDICAL OFFICER (man or woman) in the Public Health Department, for duty at QUEEN MARY'S HOSPITAL FOR CHILDREN, CARSHALTON, SURREY. Candidates must be qualified by law to practise both Medicine and Surgery in England. The salary is £500 a year, which is subject to review. The candidate appointed will be required to reside in the Hospital and to pay for board, lodging, and washing at the rate (at present £130 a year) fixed from time to time.

In the case of women, marriage terminates contract of service.

Application forms containing full details obtainable (stamped addressed foolscap envelope necessary) from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1, to whom they must be returned by April 24th.

Canvassing disqualifies.

The County Hall, Westminster Bridge, S.E.1. MONTAGU H. COX, Clerk of the London County Council.

County Borough of Sunderland.

ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

Applications are invited from fully qualified men and women for the position of Assistant Medical Officer for Maternity and Child Welfare.

Applicants must be registered Medical Practitioners, have had at least three years' experience in Public Health work since qualification, be able to show special experience in Ultra-violet Irradiation treatment, and hold a Diploma in Public Health.

Salary £600 per annum.

The appointment is subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical test as required by the Council for the purpose of that Act.

Applications, stating age, qualifications, and experience in Maternity and Child Welfare work, together with not more than three recent testimonials, should be delivered to the undersigned not later than Monday, April 21st, endorsed "Medical Officer."

Canvassing directly or indirectly, until after the first meeting of candidates, will disqualify.

H. CRAVEN, Town Clerk.

Town Hall, Sunderland.
March 24th, 1930.

Vacancies for Medical Inspectors of Factories.

The Home Secretary announces Two vacancies for Medical Inspectors of Factories (male). The scale of salary, exclusive of the cost of living bonus, is £600 per annum, rising by annual increments of £25 to a maximum of £900. The cost of living bonus at present payable on the initial salary is £176. The appointments will be subject to the usual Civil Service conditions as to retirement, pension, etc.

The Medical Inspectors will be required to undertake medical inspection, under the direction of the Senior Medical Inspector, in factories, workshops, and other places under the Factory Acts in any part of Great Britain, and to reside in such places as the Home Secretary may from time to time direct.

Candidates should be between the ages of 25 and 40, and should be natural born British subjects and children of persons who are or were at the time of death British subjects, though exception may be made in certain circumstances, of which particulars can be given on application.

Applications, on forms to be obtained from the Industrial Division, Home Office, Whitehall, S.W.1, should be forwarded so as to reach the Home Office not later than May 15th. Recommendations or testimonials will only be considered if given by persons having personal knowledge of the candidate.

The Royal Borough of Kensington.

THE LOCAL GOVERNMENT ACT, 1929.
VACCINATION.

The Council of the Royal Borough of Kensington invite applications from local Medical Practitioners who are duly qualified in vaccination work and who are willing to enter into contracts for public vaccination in the Districts of North and South Kensington respectively.

The duties will be in accordance generally with the provisions of the Vaccination Order, 1930, and subject to the approval of the Minister of Health, and the fees payable will be those laid down by the Vaccination Order with the exception that the payment authorised by Section 5 (1) (a) of the Order shall be 1s. 6d. instead of 1s. A copy of the Vaccination Order may be inspected at the Town Hall.

The contracts will be terminable by 28 days' notice on either side.

The successful candidates will not be regarded as officers of the Council, and will not be subject to any superannuation provisions.

Applications must be delivered to me not later than Wednesday, April 23rd.

Town Hall, Kensington, W.8. HORACE RAPSON, Town Clerk.

April 1st, 1930.

Borough of Luton.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Luton Borough Council invite applications for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer. Salary at the rate of £600 per annum. No bonus will be paid.

The gentleman appointed will be required to devote the whole of his time to the duties, and to act under the direction of the Medical Officer of Health.

On receipt of stamped and addressed envelope, the undersigned will supply particulars of the appointment and application form.

Applications (on such form), accompanied by copies of not more than three recent testimonials, endorsed "Assistant Medical Officer of Health," must be delivered to me by not later than Wednesday, April 23rd.

Canvassing is prohibited and will disqualify.

2, Upper George St., Luton. W. SMITH, Town Clerk.

April 12th, 1930.

City of Edinburgh.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Corporation of Edinburgh invite applications from duly qualified persons for the appointment of Medical Officer of Health for the City.

Salary £1,500 per annum, rising to a maximum of £1,750 per annum.

A Memorandum specifying the terms of appointment, and outlining the duties to be performed, may be obtained on application to the subscriber.

Applications, stating age, qualifications, and full particulars of present and past experience, should be lodged with the subscriber not later than April 26th.

City Chambers, Edinburgh. A. GRIERSON, S.S.C., Town Clerk.

March 28th, 1930.

County Council of Durham.

ASSISTANT MEDICAL OFFICER FOR PUBLIC MEDICAL SERVICES.

Applications are invited from registered Medical Practitioners, with experience in private practice, and in Poor Law Institutional and District Medical work, for the post of Assistant Medical Officer for the General Medical Services of the Council.

The scale of salary is £800 per annum, rising by biennial increments of £50 to £1,000 per annum, with travelling expenses and subsistence allowances in addition.

The officer appointed will be required to devote his whole time to the duties of the office under the control and supervision of the County Medical Officer of Health, and to reside in the City of Durham or other approved centre.

The principal duties of the post will be concerned with the Medical Services transferred to the County Council under the Local Government Act, 1929, but the officer will also be required to undertake such other Public Health work as may be allocated to him.

The appointment will be subject to the provisions of the Local Government and other Officers Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of the Act, and to the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary; and the appointment will be terminable by three months' notice on either side.

Applications, stating age, qualifications, and experience, and accompanied by copies of not more than three recent testimonials, endorsed "Assistant Medical Officer for Medical Services," must be received by the County Medical Officer, Shire Hall, Durham, not later than April 15th.

Shire Hall, Durham. HAROLD JEVONS, Clerk of the County Council.

March 31st, 1930.

County Borough of Bournemouth

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (men) for the above post. Preference will be given to candidates who have had experience in Tuberculosis and the Diseases of Children.

The salary will be £650 per annum, rising by annual increments of £25 to £700, with an additional per annum for travelling expenses, and will be subject to the usual deductions under the Local Government and Other Officers Superannuation Act, 1922.

The appointment, which will be subject to one month's notice and to the approval of the Government Departments concerned, will be a whole-time appointment under the direction of the Medical Officer of Health and School Medical Officer. The person appointed to the post will not be allowed to engage in private practice.

The duties will relate principally to School Medical Inspection and Treatment and to Tuberculosis Clinics, but the person appointed will be expected to assist the Medical Officer of Health generally.

Personal canvassing of Members of the Council is prohibited.

Applications, on forms to be supplied from this office, should be sent to me on or before April 30th, endorsed "Appointment of Assistant Medical Officer, etc."

Town Hall, Bournemouth. HERBERT ASHLING, Town Clerk.

April, 1930.

County Borough of Rochdale.

ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER (Lady).

The Health Committee invite applications for the appointment of Assistant Medical Officer for Maternity and Child Welfare.

Candidates must be fully qualified Medical Practitioners, with post-graduate experience in Maternity and Child Welfare work, and in the treatment of Venereal Diseases in Women. The officer appointed will be required to devote the whole of her time to the duties of the office, which include attendance at the Ante-Natal, Maternity and Child Welfare, and Venereal Diseases Clinics, and the Infant's and Children's Hospital. Also the inspection of and lectures to midwives, or any other Public Health duties assigned by the Medical Officer of Health, under whose direction and supervision such officer will act.

Salary at the rate of £600 per annum.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, Rochdale, and when completed should be returned, with copies of three recent testimonials, so as to be delivered at this office not later than Thursday, April 17th. Envelopes to be endorsed "Medical Officer."

Town Hall, Rochdale. WM. HENRY HICKSON, Town Clerk.

March, 1930.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

UNDER MENTAL
id HOSPITALS SUPT.

The Huddersfield Corporation invite applications from fully qualified and registered Medical Practitioners, who are also holders of a diploma in Sanitary Science, Public Health, or State Medicine for the position of Medical Officer of Health for the County Borough, with which is combined the other offices above mentioned.

The gentleman appointed will be responsible for the performance of all duties now devolving upon the Medical Officer of Health and School Medical Officer, or which may be in future assigned to him.

Candidates must not be more than 45 years of age, and the salary will be £1,100 per annum.

The successful applicant will be required to reside in the Borough, to devote his whole-time to the duties of the office, and not to engage in private practice.

The appointment is to be held in accordance with the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926, and is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, the successful candidate being required to pass a medical examination and to pay contributions at the rate of 5 per cent. to the Superannuation Fund.

Applications, stating age, qualifications, and experience, accompanied by eight copies thereof and by eight copies of three recent testimonials, and endorsed "Medical Officer of Health," must reach me not later than Saturday, May 3rd.

Applications should also give three references other than the signatories to the testimonials.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Town Hall, Huddersfield. April 5th, 1930. J. HENRY FIELD, Town Clerk.

City Mental Hospital,

HUMBERSTONE, LEICESTER.

THIRD ASSISTANT MEDICAL OFFICER AND ASSISTANT PATHOLOGIST. (Male, under 30 years of age.)

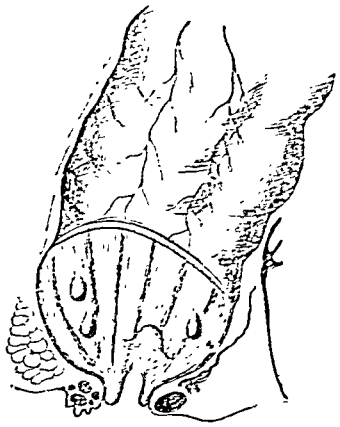
who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.



1. LONDON, EAST.—PARTNERSHIP.—A one-half share is for disposal in an old-established chiefly working-class and panel Practice, averaging about £2,800 p.a. Panel of 3,600. Visits 2/6 to 5/6. Very suitable small house, with 3 bedrooms, bathroom, etc. Garden. Rent on lease £50 p.a. Premium £2,500.
2. WITHIN TWELVE MILES OF LONDON.—In a rapidly developing residential district, offering exceptional future prospects, a mixed-class PRACTICE, averaging at the rate of £500 p.a., and increasing. Panel about 100. Visits 5/- and 7/6. Nearest opposition 2 miles. Very good detached corner house, with garden. Price, freehold, £1,800 (£1,200 on mortgage). Moderate premium.
3. LADY DOCTOR'S PRACTICE.—KENT.—Within 40 miles of London. In a town of 100,000 a well-established middle and working-class Practice, worth last year £850, including panel of 200. Visits 3/6 upwards. Mids. from 3 gns. (20 cases yearly). House, with good accommodation. Rent on lease (15 years to run) £65 p.a. Premium £1,200. Practice equally suitable for Medical Man.
4. ATTRACTIVE SOUTH COAST TOWN AND SEASIDE RESORT.—*PARTNERSHIP.—Half share of old-established and increasing* mixed-class Practice, averaging £2,390 p.a. (last year £2,527), with view to ultimate succession if desired. Appts. worth over £75 and panel of 1,500. Visits 5/- to 2 gns. Mid. 3 to 20 gns.; very few cases. Good house, with ample accommodation, at moderate rental. Premium 2 years' purchase. Held by Vendor over 30 years.
5. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
6. LONDON, S.W.—RIVERSIDE SUBURB.—Well-established mixed-class PRACTICE, averaging about £1,200 p.a., incl. panel of 850. Fees 2/6 to 7/6. No mid. Very easily worked, and good scope for enlargement. Suitable house, 6 rooms in addition to kitchen, bathroom, and professional accom. Rent on long lease, £100 p.a. Prem. £2,000.
7. DUNDEE.—Well-established PRACTICE in good residential area, offering large scope particularly for panel and midwifery. Income last year over £750 and increasing. Very well situated house, with ample accom. Price £2,800 or can be rented. Prem. £750 or near offer.
8. YORKS.—In a clean and thriving manufacturing town, an old-established Homœopathic and partly Allopathic PRACTICE, held about 50 years by Vendor who is retiring. Cash receipts for the past three years average £2,400 p.a. Patients middle and better-class. Midwifery refused. Good house available, rent £100 p.a. Premium only one year's purchase, part down and balance by arrangement.
9. SURREY.—Attractive residential district within 20 miles.—Mixed-class PRACTICE producing about £700 p.a., but capable of much increase, as neighbourhood is developing. Panel of 500. Fees 2/6 upwards. Very nice house, with 3 reception, 8 bedrooms, and three acres of garden. Rent on lease £165 p.a. Smaller house available if desired. Premium £1,200.
10. SOUTH COAST.—Popular Watering-place and Residential Town.—Old-established non-panel non-dispensing PRACTICE, held over 20 years by present Incumbent. Cash receipts last year over £2,000. Visits 5/- to 10/6. Midwifery 10 gns. upwards. Choice of several houses. Premium £2,900, or near offer, part by instalments.
11. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
12. YORKS.—PARTNERSHIP.—A one-third share, with increase later, is offered in a sound and increasing middle and working-class Practice, situated in prosperous district close to two good towns. Average gross cash receipts for past three years £3,226 (last year £3,554). Panel of 2,100, and appts. worth over £130. Good house, with 2 reception, 4 bedrooms, etc. Large garden and paddock. Garage. Price £1,900. Premium for share 1½ years' purchase.
13. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—Old-established mixed general PRACTICE. Average income nearly £1,900. Panel of 2,500. Fees 2/6 to 7/-. No mids. No Assistant kept. Well-situated house, with good accommodation. Rent on lease £120. Prem. £3,300.
14. WITHIN 40 MILES OF LONDON.—In a thriving Riverside and Hospital town (pop. over 40,000).—Old-established mixed-class and increasing PRACTICE worth over £2,300 last year, including panel of 1,000 to 1,700. House contains professional accommodation, 2 reception 4 bedrooms, bathroom, etc. Small garden and garage. Rent on lease £60 p.a. Premium £3,650, to include good book debts of £500, drugs, etc., and consulting room and surgery furniture.
15. WITHIN FIFTY MILES OF LONDON.—Old-established Country PRACTICE, within easy reach of attractive County Town. Income over £1,200, including panel of nearly 800. Visits 5/- upwards, medicine extra. Very nice house, with ample accommodation (6 bedrooms, etc.) and good garden. Rent on lease £80 p.a. Premium £1,600.
16. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACT[illegible] past three years £904 p.a. (last year £973), [illegible]0. Visits 5/- to 12/6, medicine extra (3/6). One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Water laid on and gas plant installed. Rent £50 p.a. Premium £1,400. Excellent sport.
17. CROYDON AREA.—PARTNERSHIP.—A two-fifth share, to commence with, in an old-established good middle-class Practice, producing an income of about £2,750, including panel of nearly 1,000. Fees 5/- to 10/6. Convenient house can be obtained on lease at a rental of £80 p.a. Premium 2 years' purchase.
18. PARTNERSHIP.—WEST MIDLANDS.—The Third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional fertility. Cash receipts average £2,367 p.a., including panel of 1,084. Opposition not strong. Expenses light. Choice of two houses (small and large) can be bought for £600 or £700. Premium 2 years' purchase.
19. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1¼ acres. Price, freehold, £3,500. Premium 1½ years' purchase.
20. SOUTH-WEST OF ENGLAND.—Old-established and increasing PRACTICE in pretty district 5 miles from Hospital town and within 10 miles of the sea. Income last year £1,489, including Xmas, etc. (£105) and panel of 780. Railway station near. Detached house (professional rooms, 2 reception, 5 bedrooms, bathroom, etc.) Garden. Garage. Rent on lease £45 p.a. Premium £2,100.
21. LONDON.—EASTERN SUBURB.—Old-established good middle-class PRACTICE averaging about £1,350 p.a. Panel of 715. Fees 3/6 upwards. Not much midwifery. Exceptionally nice house, with large garden, tennis court, etc. Contains 10 rooms, in addition to bathroom, etc., and professional rooms. Two garages. Rent on lease £120 p.a. (upper part well let off). Premium £2,000.
22. WITHIN FIFTY MILES OF LONDON.—In a pretty residential district, a well-established PRACTICE averaging over £700 p.a., including panel of 538, and appts. worth about £60. Visits 3/6 to 21/-, *medicine extra*. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Elec. light. Price for freehold £3,000. Premium £1,050. Exceptionally good educational facilities for boys.
23. LARGE UNIVERSITY CITY (WEST).—Good-class old-established non-dispensing PRACTICE worth last year £1,274, including select panel of about 350. Visits up to 21/-. Very little midwifery. Good house in best part of City, overlooking park, with ample accommodation. Vendor's freehold, but will be let on lease. Premium only £1,000.
24. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, experienced, 30 to 35 years of age and married preferred) can acquire a share (freehold) at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house with ample [illegible] etc., on rental. Premium 2 years' purchase [illegible] assistantship essential.
25. SOUTH-WEST [illegible] HOSPITAL TOWN.—[illegible] share in an old-established mixed-class PRACTICE is offered owing to the retirement of the Junior Partner. Gross cash receipts average £2,300 p.a., including good appts. Small panel. Low expenses. Commodious house, with garden and garage, rent £70 p.a. Premium 2 years' purchase. Vendor on staff of Hospital, and scope for same.
26. YORKS.—LARGE TOWN.—Very old-established middle and working-class PRACTICE, offering exceptional scope for increase. Income for last year £1,500, including panel of over 1,700. Visits 4/6 to 5/-. Conveniently situated house, with 2 reception, 4 bedrooms, etc. Rent on lease £56 p.a. Premium £2,250.
27. SOUTH DEVON.—PARTNERSHIP.—Attractive Town close to sea. Half share in very old-established and rapidly increasing mixed general Practice. Average cash receipts last 3 years £2,727, last year £3,523. Panel of 1,130. Fees 3/6 to 21/-. Good house in its own grounds with ample accommodation. Price freehold £1,900. £1,200 on mortgage. Prem. £2,300. Cottage Hosp. and good scope for major operations.
28. PARTNERSHIP.—OXON.—Delightful residential district, near [illegible] town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,5[illegible] and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 2 years' purchase.

The Haemorrhoidal Circle

Internal and external hæmorrhoids, resulting from pressure upon the blood vessels and obstruction of the circulation in the rectum.

DISTENTION of the rectum from painful defæcation—pressure on the rectal blood vessels — impeded circulation — hæmorrhoids. Cathartics to relieve the constipation —irritation of the mucous membrane and the existing hæmorrhoids — pain — possible anal fissure — cessation of purging—constipation.

Such is all too frequently the vicious circle of dyschezia and hæmorrhoids, a combination which requires appropriate local treatment and a bowel corrective that will not irritate.

AGAROL Brand Compound, the original emulsion of mineral oil, agar-agar and phenolphthalein, is pre-eminently indicated for the correction of the vicious circle.

AGAROL Brand Compound lubricates, therefore prevents irritation by friction; it segments and softens the fæcal mass, and thereby prevents possible excessive strain in the expulsion of it; it stimulates the peristaltic force without the shock of cathartics.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion with Phenolphthalein and has these advantages

Perfect emulsification, stabilized, pleasant taste without artificial flavouring, free from sugar, alkalies and alcohol, no oil leakage, no griping or pain, no nausea, not habit forming

A liberal quantity sent to physicians on request.

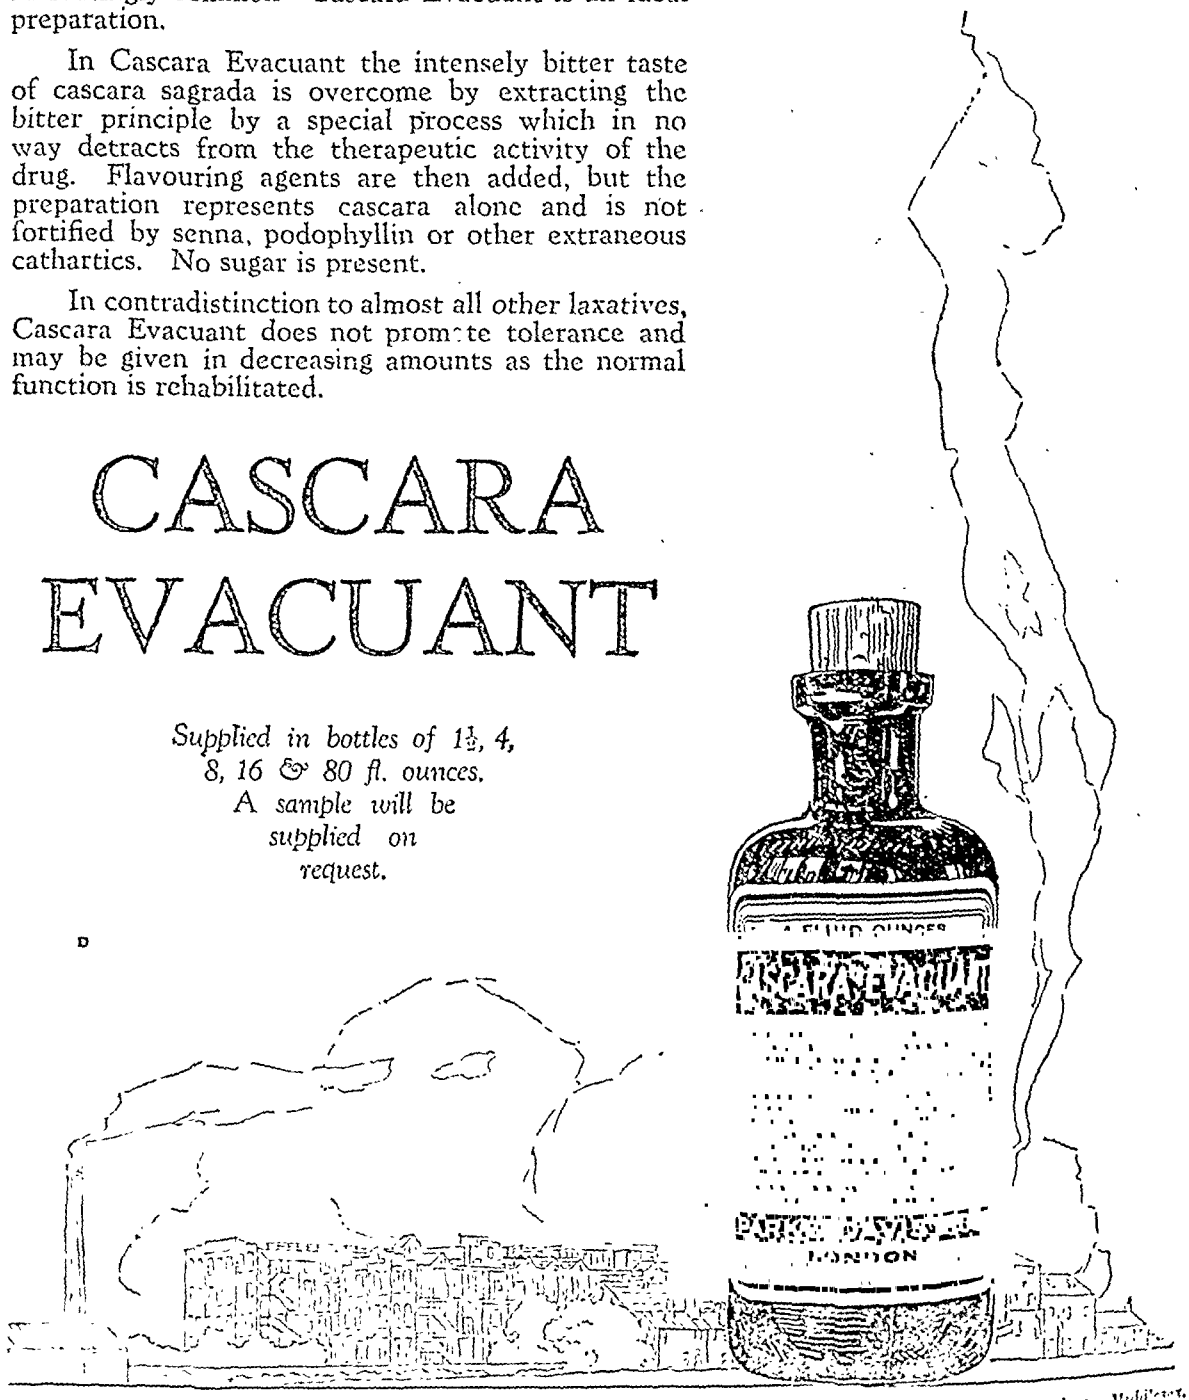
In Intestinal Torpor

Cascara Sagrada was introduced to the medical profession by Parke, Davis & Co. in 1877.



FOR those cases in which a laxative that will directly stimulate contraction of the intestinal muscle is required—and such cases are becoming increasingly common—Cascara Evacuant is an ideal preparation.

In Cascara Evacuant the intensely bitter taste of cascara sagrada is overcome by extracting the bitter principle by a special process which in no way detracts from the therapeutic activity of the drug. Flavouring agents are then added, but the preparation represents cascara alone and is not fortified by senna, podophyllin or other extraneous cathartics. No sugar is present.

In contradistinction to almost all other laxatives, Cascara Evacuant does not promote tolerance and may be given in decreasing amounts as the normal function is rehabilitated.

CASCARA EVACUANT

Supplied in bottles of 1½, 4, 8, 16 & 80 fl. ounces. A sample will be supplied on request.

Bismuth-Formic-Iodide Compound

Mulford B-F-I

Supplied in 2 sizes in sprinkler-top tins.

Bismuth-Formic-Iodide Compound, now well known as "B-F-I", is a medicated dusting powder possessing soothing, astringent and antipruritic properties. It is a safe, dry dressing that promotes healing and has been widely used for thirty years by physicians and in hospitals.

B-F-I has the capacity for absorbing fluid from the surface, thereby exerting a drying action. It does not cake or form hard crusts, which would only add to the irritation. B-F-I is, therefore, the ideal dusting powder for use wherever excoriation and a weeping surface occurs.

This compound has been found very satisfactory and effective in treating superficial wounds, eczema, impetigo, pemphigus, ulcers, burns, abscesses, vaccination area, bed or fever sores, chafing, abrasions and similar skin irritations.

Physiology of the Central Nervous System and Special Senses

(For the use of Students.)

By N. J. VAZIFDAR, L.M. & S., F.C.S., F.C.P.S.,

Assistant Chemical Analyser to Government of Bombay; Fellow of the Indian Chemical Society; Examiner in Physiology and Examiner in Medical Jurisprudence, College of Physicians and Surgeons, Bombay; Examiner in Chemistry and Examiner in Medical Jurisprudence and Mental Diseases in the University of Bombay.

FIFTH EDITION. WITH THIRTY ILLUSTRATIONS.

EXTRACT FROM REVIEWS OF PREVIOUS EDITION.

A careful compilation, Dr. Vazifdar's book is intended to help students through their intermediate examination and it covers the ground adequately.—*British Medical Journal.*

This is an admirable abstract or résumé of a description of the physiology of the Central Nervous System and the Special Senses. The abstract is based upon well-known textbooks of physiology and is accurate and up-to-date in its information. The author may be congratulated on having produced a book of distinct utility to the Indian students. Being a résumé the book is useful to students and practitioners for revision and reference purposes. There are numerous diagrams and tabular statements which help not only in grasping the facts, but in remembering them. The popularity of the book is well deserved.
—*The Indian Medical Gazette.*

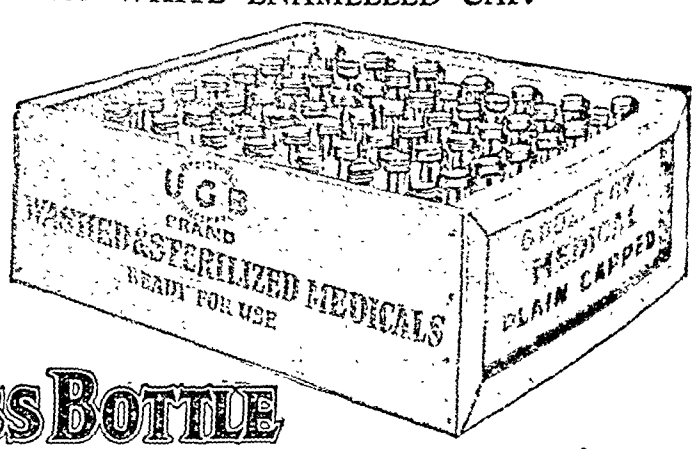
The U.G.B. MEDICAL BOTTLE Service



Photograph of actual package of Cork-mouth bottles with cover removed.

THE U.G.B. Washed and Sterilized medical bottle service—introduced early in 1929—has proved to be an unqualified success, so much so that we were recently compelled to increase the capacity of our washing and sterilizing plant.

The screw cap service is in particular demand, and owing to the preference of users for a cap in a neutral colour, we have now standardized in fitting the bottle with an attractive RUSTLESS WHITE ENAMELLED CAP.

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

The Association's Report, dated June, 1929, states that the Iron as ferrous sulphate occurs in these samples in proportions varying from 170 to 1,275 grains per gallon, combined with Aluminium Sulphate and free Sulphuric Acid.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 2 grains of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

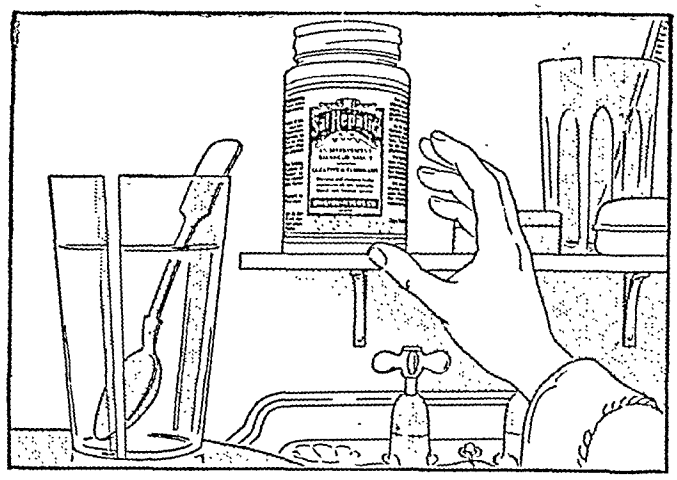
Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures:—

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable.

Close co-operation is maintained with the patient's own physician.



Further particulars may be obtained at Belle Vue Spa or 7, Harley Street, W 1.

In all cases of auto-intoxication

Diabetes, rheumatism, gout, sciatica, lumbago, neuritis and many other similar diseases have been found to have their origin in auto-intoxication, which gives rise to acidosis. ¶ The speedy and thorough evacuations induced by Sal Hepatica expel all auto-intoxicants from the system, while the blood and urine is rendered alkaline. ¶ Sal Hepatica stimulates the biliary flow, thereby relieving hepatic congestion, and restores the daily habit of defecation by natural means. It is non-habit-forming, non-irritant and entirely painless in its action. Sal Hepatica is only advertised to the medical profession.

Local Anæsthesia in Surgical Practice

CERVICAL ADENITIS.

Typical Case.

The following case will illustrate the application of Local Anaesthesia in children in whom the establishment of General Anaesthesia would seem especially hazardous

D. D., aged 9 months.

Diagnosis: Suppurative cervical adenitis.

Operation: Incision and drainage.

Anaesthesia: Local infiltration, 20 c.c. of a 0.5 per cent. Novocain-Adrenaline solution.

Operation: A direct infiltration was made over the swelling, using 20 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution. The skin was picked up with towel pins to avoid pressure and a transverse incision was made down to the cervical fascia. At this point the operation was delayed when the cervical fascia was infiltrated. This layer was then picked up with towel pins and a sharp-pointed hemostat was forced through and spread widely, opening the abscess. —EXTRACT from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

OVALTINE

MILK AND ITS DEFICIENCIES.

In the dietary of fevers and infectious diseases milk probably holds the most important position for one reason, that it leaves a residue which is not mechanically irritating.

Milk, however, has certain objections. It is deficient in carbohydrate; it is also repugnant to many people and rapidly becomes tiresome to others.

"Ovaltine" improves milk as a nutritional agent wonderfully. It relieves the monotony of a milk diet. Further, the addition of "Ovaltine" to milk not only makes it more attractive to the taste, but raises the nutritive power and renders the milk twice as digestible—valuable features where dyspepsia is associated with constitutional disturbance.

"Ovaltine" adjusts the carbohydrate deficiency in cow's milk and converts the curd into a light, flaky, easily digested coagulum. It also provides nutriment of inestimable value for maintaining adequate nutrition.

A liberal trial supply will be sent to members of the medical profession in private or hospital practice.

The Treatment of Pulmonary Affections by Inhalation.

THE AËRISER

This instrument converts liquids into a voluminous but almost invisible vapour, or, in the words of the "LANCET," it "renders fluids like smoke," and thus enables medicated vapours to be inhaled continuously without injury to the delicate mucous lining of the air passages.

In all other sprays, atomisers, inhalers, etc., the spray is given off in palpable particles and cannot be used long without giving rise to discomfort. With the Aëriser, however, solutions, whether aqueous, oily, or balsamic, are given off in such a state of fine division that when the vapour is directed on to a sheet of glass or paper it remains unsoiled; consequently, when inhaled the medicament reaches the whole of the respiratory tract even to the innermost recesses of the lungs without causing the slightest irritation.

3 DAYS TO LIVE!

Humanised Trufood saved him!

47, Spencer Street,
York Street,
Belfast.

"Dear Sirs,

I owe my baby's life to Humanised Trufood. He was given up and had three days to live at birth. He is a premature eight-months' baby, weighed 3½ lbs. when born. We put him on . . . . . and several other foods, but he made no progress.

I took him to Dr. . . . Children's Hospital. He told me to get Humanised Trufood on my way home. I can honestly say from his first feed I saw a change. He is now walking, has cut six teeth, never had one teething powder, is full of fun and mischief."

Yours truly,
Mrs. J. Reid.

We openly invite the medical profession to adopt Humanised Trufood for their troublesome cases. There is a reason for this—

The difficult cases of infant feeding prove the worth of Humanised Trufood

TRUFOOD LTD., THE CREAMERY, WRENBURY, Nr. NANTWICH, CHESHIRE.

Viosterol "A. & H."

Irradiated Ergosterol *(Vitamin D)* in Oil

Biologically Standardised

Viosterol "A. & H." is standardised to contain 10,000 units of Vitamin D in each c.c., i.e., it possesses 100 times the Vitamin D activity of good Cod-Liver Oil.

Viosterol "A. & H." is the specific treatment for rickets, tetany and other disturbances of the calcium-phosphorus metabolism.

Special advantages of Viosterol are the small dosage required, its prompt effect, palatability and absence of digestive disturbances.

Viosterol "A. & H." is issued in special rod-stoppered bottles containing 5 c.c. and 50 c.c.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3 6, 8 6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Decrease of the "Alkali Reserve"

A palatable, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium.

is directly responsible for a large proportion of those ills which are manifestations of hyperacidity. Effective alkaline treatment is imperative. Alka-Zane, antacid and diuretic, promptly neutralizes the excessive acid products and rapidly restores the normal alkalinity of the blood.

A brief trial will demonstrate the efficiency of

ALKA-ZANE

RADIOSTOL

The Original British Irradiated Ergosterol

From the time Radiostol was first supplied to members of the medical profession more than three years ago it has been regularly tested biologically in the B.D.H. laboratories, and standardised to a definite Vitamin D activity. The unitage adopted for expressing this activity is that described by Coward (*Quarterly Journal of Pharmacy*, Vol. I, 1928, p. 27), the activity of Radiostol solution being maintained at 10,000 antirachitic units per c.c. and that of Radiostol pellets at 6,000 antirachitic units per pellet.

This standardisation of activity of both solution and pellets has brought Vitamin D therapy within the range of an exact medical science. On this account the administration of Radiostol has become the routine method for preventing and correcting the effects of Vitamin D deficiency.

The non-toxicity of Radiostol is a further point of signal importance, its administration even in large excessive doses over a long period being quite harmless.

THE BRITISH DRUG HOUSES LTD. **LONDON N-1**

Vit. Pr 92.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

Disturbances of Menstruation and the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases.

The chemical composition of Kalzana, calcium - sodium - lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had 'acute dysmenorrhoea; this is cured apparently."

Kalzana is supplied in a convenient tablet form, is free from harmful by-effects and is pleasantly flavoured.

Dispensed by Chemists in air-tight packets containing 50 and 100 Tablets.

Kalzana

Exactitude in preparing Milk Mixtures

very often solves the most difficult problems set by the artificially-fed infant. Careful dilution of cow's milk will give the correct percentage of casein, and the addition of Albulactin provides exactly the proportion of lactalbumin needed to meet the digestive capacity of the infant. Albulactin is pure soluble lact-albumin—the vital proteid of milk—upon which depends the formation of a fine, flocculent curd in the infantile stomach. Albulactin simplifies the preparation of milk mixtures for all infants, from the premature weakling to the normal healthy baby.

"The British Medical Journal" says:

"A modified milk, prepared by mixing cow's milk, albulactin, and water in such proportions that the casein and albulactin were in approximately equal amounts, formed much less curd when acidified than diluted cow's milk, containing the same proportion of total protein. There appears to be every reason to expect this preparation to be of great value in the hand feeding of infants."

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO. (Foreign Produce.)

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available on special terms.

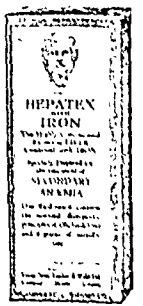
Wulfing Products



HEPATEX (*Aesculapius*) **WITH IRON**

TREATMENT OF

Severe Secondary Anæmias

For the treatment of the severe secondary anæmias the use of liver in itself is of inconstant value. Likewise the administration of iron, while undoubtedly beneficial, does not always ensure that degree of improvement which is desirable. Liver and iron combined, however, have proved most effective.

HEPATEX WITH IRON provides a rational treatment for severe secondary anæmias. One drachm contains the essential therapeutic principles of 2 ozs. liver and 1 grain of iron. This iron, compared with ordinary iron preparations, is greatly superior as regards assimilation and absence of gastro-intestinal disturbances.

Issued in 2-oz. bottles, 7/6 each.

Vaccines and Sera

Vaccine Lymph

Compound Catarrhal Vaccine	In phials containing 235, 470, 940 and 1,880 million organisms per c.c.
Compound Influenza Vaccine	In phials containing 330 and 660 million organisms per c.c.
Micrococcus Catarrhalis Vaccine	In phials containing 25, 50, 100 and 250 million organisms per c.c.
Concentrated Tetanus Antitoxin	In phials of 1,000 to 40,000 units (=500 to 20,000 U.S.A. units).
Concentrated Diphtheria Antitoxin	In phials of 500 to 10,000 units.
Anti-Streptococcus Serum	In phials of 10 and 25 c.c.
Anti-Meningococcus Serum	In phials of 10, 15 and 30 c.c.

A descriptive pamphlet, issued under the Authority of the Governing Body of the Lister Institute, will be sent on request.

MONSOL
in
MIDWIFERY

The antiseptic employed in midwifery must be both germicidally powerful and at the same time safe and free from danger.

Monsol is the ideal preparation in such cases because:—

(1) *It is selective in its action on streptococcal bacteria, being 10 times as powerful as lysol in this respect.*

(2) *It has a perfectly non-irritant action on the tissues and mucous membranes at therapeutic concentrations.*

(3) *It keeps the hands and skin soft and does not roughen them.*

(4) *Is is a standard product and never varies in composition.*

Authorities competent to judge have expressed the considered opinion that the use of Monsol in midwifery reduces the incidence of puerperal sepsis by fully 90%.

Other authorities have also stated that certain lysol and cresylic acid preparations are not efficient germicides against streptococci without being used at concentrations which involve grave risk of injuring the tissues.

Monsol is so bland in action that it can safely be used at strengths far greater than germicidally necessary without any risk of causing irritation.

MONSOL PREPARATIONS INCLUDE:
MONSOL LIQUID, OINTMENT, INTERNAL CAPSULES, PASTILLES, DENTAL CREAM, TOILET SOAP, ETC.

Manufacturers:
The Mond Staffordshire Refining Co., Ltd.
Abbey House, London, S.W.1.

TRADE MARK 'WELLCOME' BRAND

LIVER EXTRACT

(An Active Selected Fraction of an Extract of Fresh Liver)

Prepared by a process tested and found efficient by the Medical Research Council. Clinical reports continue to present evidence of the prompt response to the administration of 'WELLCOME' LIVER EXTRACT in pernicious anæmia.

Liver treatment is valuable in cases of secondary anæmia due to hæmorrhage, such as hæmatemesis or post-partum hæmorrhage. Also suggested in conditions due to liver dysfunction and in the vomiting of pregnancy and pre-eclamptic conditions.

In tubes, each containing an active selected fraction of an extract derived from half-a-pound of fresh liver.

DIRECTION.—

The contents of one tube, or more, daily, in soup or water.

Price in London to the Medical Profession
32/5 *per box of* 12 *tubes*

FIGURED SILK DESIGNED AND WOVEN BY BYZANTINES.—The production of raw silk in Europe was the direct outcome of an effort on the part of the Byzantines to break down the Persian monopoly in the traffic in silk from China to the west. The secret of its production had been jealously guarded in China, but in the sixth century two monks who had lived in that country visited Justinian in Constantinople, revealed to him the whole process, and suggested that they should endeavour to smuggle away some silkworm eggs, since they believed the worms would thrive upon mulberry trees as well in Europe as in China. The Emperor offered them a rich reward and they succeeded in introducing the eggs concealed, it is said, in a bamboo cane. Mulberry trees were planted, especially in Syria and Greece, and sericulture began in earnest. The piece of silk here reproduced shows a design inspired from antique sources—Hercules, or, perhaps, Samson, struggling with the lion.

Fresh cows' milk is *not* naturally rich in Vitamin D

"Ordinary milk sold throughout the greater part of the year contains almost no anti-rachitic vitamin."

The Lancet, Nov. 23, 1929, p. 1090.

* * *

† Untreated milk both whole and skimmed, has very little anti-rachitic activity. (†i.e. Ordinary fresh cows' milk.)

The Lancet, Jan. 18, 1930, p. 129.

* * *

* "Vitamin D, the anti-rachitic or calcifying vitamin, ranks first in importance in calcifying processes. If there is an abundance of this substance present in the diet, well calcified teeth will be formed" .... "Without vitamin D perfect calcification will not take place, however much calcium and phosphorus is given in the diet."

* *MEDICAL RESEARCH COUNCIL MONOGRAPH, "DIET AND THE TEETH" 1929 p. 304.*

These authoritative quotations are convincing that fresh cows' milk contains "almost no vitamin D." It follows that a food made from fresh milk contains "almost no vitamin D." This vital constituent of a baby's dietary is added to Sunshine Glaxo in a definite quantity determined by more than two years' trial under the supervision of specialists in infant dietary. Clinical experience proves that as a result of this addition Sunshine Glaxo builds firm flesh, strong bone, sound teeth and eliminates constipation and the dangers of fat intolerance.

SUNSHINE GLAXO

with added "Ostelin" vitamin D

Further information on Sunshine Glaxo and "Ostelin" Vitamin D products supplied on request to:

A British Medical Association Lecture

ON THE

RELATION OF MEDICINE TO SURGERY IN THE TREATMENT OF GASTRIC AND DUODENAL ULCER.

DELIVERED AT SWANSEA ON FEBRUARY 27TH, 1930,

BY

CHARLES BOLTON, C.B.E., M.D., D.Sc.LOND., F.R.C.P., F.R.S.,

PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

THE treatment of gastric and duodenal ulcer has probably occasioned more difference of opinion within recent years than that of any other single disease, both as regards the relative parts that medicine and surgery should play in it, and also as to what method or operation should be adopted, when either the one or the other treatment has been decided upon. The view of the physician is biased by the number of surgical failures which he sees, and that of the surgeon by the many cases he operates upon which have been medically treated after some fashion or other, generally inadequately, for years. The usual method of arriving at a decision is to compare statistics of cures, and certainly many surgical statistics show impressively high figures: no one can expect 100 per cent. successes, and it is urged that these figures speak for themselves, some enthusiasts believing that peptic ulcer is really a surgical disease and that medical treatment is of little avail. This relation should not, however, be decided by statistics of this kind, which cannot be rightly compared with each other, because the functions of medicine and surgery are different in that they should be concerned with different types of cases. As I shall point out later, most ulcer cases one sees have never had an adequate medical treatment, so that it seems reasonable to assume that surgical statistics are swelled by the inclusion of simple cases easily curable by medical means; on the other hand, those of medicine include many incurable chronic cases, which must be given the opportunity for healing before they can be pronounced incurable, owing to the difficulty of foretelling the condition of any particular ulcer. I have therefore no intention of bringing forward and discussing medical statistics with any other idea than to use them in support of the points I wish to raise. Instead of competing in a statistical race, we should make it our business to inquire, in greater detail than is afforded by the comparison of rough statistics, as to what are the precise functions of medicine and surgery in the treatment of this malady, and what is the most advantageous distribution of their shares in this work. If, with this end in view, we take a broad survey of the life-history of ulcer we shall realize that all the old thickened ulcers, which we hand over to the surgeon, have been originally acute and easily curable by medical means, and that during their evolution they have passed through similarly curable stages before reaching their final surgical destination. In my view ulcer is primarily a medical disease; its possessor consults, in the first instance, the practitioner of medicine, using this term in its widest sense, who should make the diagnosis, and successfully treat the bulk of the cases. He should hand over to the surgeon the recognized operable complications, and the uncomplicated ulcers which obstinately resist his treatment; and to his lot falls the treatment of the post-operative invalids. I shall first give you the facts, which are matters of common knowledge, in support of my view that ulcer is a medical disease, and can be successfully treated by medical means; I shall then describe what is meant by an adequate medical treatment; and, finally, I shall indicate what uncomplicated cases should be dealt with by the surgeon, and what we expect of him.

I. ULCER IS PRIMARILY A MEDICAL DISEASE.

(A) I have elsewhere pointed out that there is no pathognomonic symptom of gastric and duodenal ulcer[1]; and, indeed, it is self-evident that if we could certainly diagnose the condition by symptoms we should not resort to all the tests necessary for an exact diagnosis. The malady simply gives rise to various forms of dyspepsia, depending on its situation and indistinguishable from similar forms of dyspepsia due to other causes. It acts as a focus of irritation to the part of the apparatus in which it is situated, and induces pain, as all other causes do, referable to that particular part. I have already recorded thirty-three cases in which the symptoms so closely resembled those of ulcer as to be mistaken for them, and yet at the operation undertaken for the supposed ulcer no lesion was to be found in any part of the abdomen. The patient appears for diagnosis among a host of dyspeptics. His symptoms may or may not suggest ulcer, and in many cases we may accurately forecast the diagnosis by the regularity, severity, and clear definition of the pain; but no absolute diagnosis can be made in the absence of confirmatory tests. The difference is one of degree and not of kind. The patients have therefore to be sorted out of a multitude of medical cases complaining of similar symptoms, and this is the business of the physician. The ulcer may be, and not uncommonly is, beyond the hope of benefit by medical treatment when first seen, but it would have healed if it had been recognized in its earlier stages and afforded the opportunity.

(B) The development of ulcer shows that it has, indeed, passed through such intermediate stages. Too much attention is commonly focused upon the old chronic types to the neglect of these earlier and more curable forms. Unless one takes a broad view of the malady the relation of these early stages to the final chronic stage is not recognized. Each ulcer has a definite life-history, and may appear for diagnosis at any stage in its origin, evolution, or cicatrization. Many years ago I demonstrated the origin of chronic ulcer from the acute variety,[2] and pointed out that acute ulcer arising as a localized lesion in most cases heals normally; that the healing may be delayed for different periods of time; or that it may be arrested, when thickening and irregular extension convert it into a chronic ulcer. A second type of acute ulcer beginning at one point spreads rapidly in a circular fashion, destroying one coat of the stomach after the other. At any stage its extension may be arrested and healing occur; or it may thicken and, with or without the exposure of an organ to which it adheres, become chronic. A whole series of different types of ulcer are thus presented to the clinician for diagnosis, and success in medical treatment depends upon its early and efficient application. If all ulcers were thus treated there would be left no chronic ulcers or their complications for the surgeon to operate upon.

II. AN ULCER CAN USUALLY BE SUCCESSFULLY TREATED BY MEDICAL MEANS.

A.—*Clinical Evidence.*

Statistics to be of real value should show: (1) that an ulcer was originally present; (2) that it has been adequately treated; (3) that no test can subsequently prove its presence. No large series of follow-up cases answering all these requirements is to hand, the method of relying upon the patient's statement, as to whether he has had any symptoms or not since the treatment being adopted. If none at all, he is said to be cured: if symptoms occasionally, but not enough to call a relapse, he is said to be improved.

(1) *As Regards the Healing of the Ulcer.*

The immediate results of one of the recognized methods of treatment—and it does not matter much which is employed—are uniformly excellent. The pain rapidly disappears and the patient leaves his bed and becomes convalescent without symptoms in almost 90 per cent. of cases. If the pain does not subside some complication is present, the ulcer is an old chronic one, or there is a good deal of superadded nervous irritability of the stomach. Many of these ulcers are healed, many are advanced in healing, and some are unaltered. Now the knowledge we wish to obtain is twofold: (1) the percentage of the various types of ulcer which can be directly healed by medical treatment; and (2) what proportion of these patients can be protected from recurceration of the scar, or the formation of a new ulcer. We already know that an acute ulcer of moderate size takes from two to three weeks to heal, and

a subacute or chronic one from a few weeks to months. Some indefinite time after the treatment must therefore be allowed to elapse before the ulcer can be said to have healed, unless, of course, the healing is proved by tests. A time limit of this sort can only be approximate, and perhaps in most cases twelve months would be sufficient. If this time limit be selected we must regard all the cases without symptoms and many improved cases—that is to say, which have not had a relapse within this time—as being healed. The difficulty, of course, is that the absence of symptoms does not necessarily imply that the ulcer is healed. The carefully observed cases of Einhorn and Crohn[3] show the following results.

Time after Treatment.	Cured.	Improved.	Total.
1 year	67.5 per cent.	22.0 per cent.	89.5 per cent.
2 years	53.6 „	10.0 „	66.6 „
3 „	41.2 „	23.5 „	64.7 „
4 „	27.3 „	22.7 „	50.0 „

Taking the time limit for healing as one year, it appears that at least 70 per cent. were healed. Their statistics show very little difference between gastric and duodenal ulcers. The duration of the illness before treatment, or, in other words, the age of the ulcer, should be taken into account, and we should remember that a certain proportion of the improved cases which have had no definite relapse are without doubt healed. It is perhaps a fair statement to make that practically every acute ulcer, if efficiently treated, would heal, and that three-quarters of the subacute and moderately chronic ulcers would likewise heal, but that with increasing chronicity the probability of healing markedly diminishes.

(2) *As Regards the Prevention of Future Ulceration.*

Statistics dealing with longer time limits after the treatment refer more particularly to the liability to future ulceration. The statistics quoted above demonstrate that the percentage of cures diminishes with the lapse of time. According to Nielsen[4] about 88 per cent. of the relapses occur within the first two years, after which time up to the limit of his observations—that is to say, eighteen years—there is only a small liability to recurrence. He therefore took the time-limit of two and a half years, and worked out in a series of cases the number of cures within this period of time, according to the age of the ulcer. His results are as follows:

Duration of Illness.	Cured.	Improved.	Total.
6 months ...	60.0 per cent.	16.7 per cent.	76.7 per cent.
½-1 year ...	54.1 „	16.7 „	70.8 „
1-3 years ...	35.9 „	21.0 „	57.9 „
3-5 „ ...	20.0 „	26.7 „	46.7 „
5-10 „ ...	10.8 „	10.3 „	21.6 „
Over 10 ...	5.3 „	17.6 „	22.9 „

This is perhaps the most important series of cases hitherto published. They demonstrate the important fact that in the case of moderately recent ulcers a permanent freedom from relapse can be guaranteed in at least 54 to 60 per cent., or, including some of the improved patients, 60 to 70 per cent. of cases. They also show that the old chronic type is the least curable, for if the duration of the illness be five years and upwards the probability of a permanent cure is only, on the average, 10 per cent. The reason for this is because the scar of an old ulcer is unsound and the covering epithelium easily re-ulcerated.

Crohn concludes that four years after the treatment over 70 per cent. of patients with a duration of illness up to six months are cured, but only 37 to 47 per cent. of those with an illness duration of from one to twenty years. Setting aside the strict accuracy of these statistical figures, they give us the information that if ulcers were treated at a fairly early stage of their existence not only would the prospect of healing be excellent, but the risk of future ulceration would not be great. If, however, they have been untreated for five years or so the prospect of a permanent cure is poor. There are many series of statistics which have been published from time to time, dealing with mixed types of cases followed for varying periods, but not analysed year by year nor as to the chronicity of the ulcer. They show very varying percentages of cures, some high and some low. In a general sort of way their figures agree with those quoted above in showing that the longer the period of observation the smaller the number of cures. I believe that Nielsen's deductions, so far as statistics are able, give us the required information as to the possibilities of medicine and the reasons why it fails.

It is quite evident that our failure as regards *the actual healing of the ulcer* is due to neglect of the treatment in the early stages of the malady. We do not begin treatment early enough. It is unfortunately the fact that ulcer patients who have really been properly treated by medical means are in the minority, however long they have been ill. They have had numerous bottles of alkalies medicine, and perhaps a week in bed now and then when the pain was of unusual severity, but no systematic treatment by one of the recognized methods. This is neither altogether nor perhaps usually the fault of the medical attendant, because it is remarkably difficult, for one reason or another, to induce patients to undergo prolonged treatment in bed. Unless they are suffering from acute pain they are difficult to convince of the necessity for energetic treatment. It is perhaps better for the patient if he bleeds, for then bed is a necessity; even in such cases one not uncommonly sees patients who have only been in bed for one or two weeks. The same remark apply to the question *of the prevention of recurrence*, since this again also depends upon the age of the ulcer and when treatment is commenced. There is perhaps a greater difficulty in the way, because, having restored the general health, and regulated the habits and diet of the patient, we are at his mercy as to whether he carries *out our advice. It is only a certain* number of patients who will conform to dietetic and other rules when they have been free from symptoms for a certain length of time. The fulfilment of this condition is, however, perhaps of as great importance as the early treatment of the ulcer.

B.—*Pathological Evidence.*

(*a*) Scars of former ulcers are often found at *post-mortem examinations*. There are several old series of statistics which show that scars and ulcers are present with equal frequency. Others give the *proportion* of scars to ulcers as 2 to 1 or 3 to 1. More recently Stewart has paid special attention to this subject, and in 4,000 necropsies found chronic gastric ulcers in 2.2 per cent. and scars of chronic ulcers in 2.3 per cent. This is very valuable information, for it shows that 50 per cent. of chronic ulcers undergo spontaneous healing, and that healing of acute and subacute *ulcer is well known* to occur more easily than that of the chronic variety. Stewart found the scars of duodenal ulcer to occur with about the same frequency as open ulcers (2.8 to 2.5). Ulcers heal more easily than these figures indicate, for in such statistics there is no knowledge of the opportunity for healing which has been afforded to most of them, and it seems probable that all these ulcers—did *not* have the benefit of adequate medical treatment. Here again we see that more recent ulcers were included in the list healing which probably occur in not far short of three-quarters of the cases.

(*b*) *At an operation* undertaken for a supposed ulcer, a scar is not uncommonly found in its place; either the ulcer has already healed owing to postponement of the operation, or the pain was due to nervous irritability of the stomach, which had been previously the subject of an ulcer. Many examples of this kind, both gastric and duodenal, have come under the notice of physicians. I have had four such experiences myself, three of them being

duodenal. It is also a well-known fact that excised ulcers are frequently found to be advanced in healing.

(c) In death from *gastric haemorrhage* I have already pointed out that, in the case of acute ulcer when the patient has survived for a time, the ulcer will be invariably found to be rapidly healing, and in some cases it is healed up to the mouth of the bleeding artery, which thus appears to be embedded in the centre of a scar.[6] In another class of case, fortunately rare, of which I have seen two examples, during the systematic treatment of a more chronic ulcer a sudden haematemesis has carried off the patient. The ulcer base was filled with granulation tissue, and the mucous membrane all round extended on to the base in a perfectly normal manner. An artery in the centre had suddenly commenced bleeding.

C.—*X-Ray Evidence.*

The *disappearance of the ulcer niche* under medical treatment occurs commonly enough, and is valuable evidence of the healing of gastric ulcer, but unfortunately it is of little use in duodenal ulcer. Since Ohnell in 1917[7] published his cases of niche disappearance as a sign of healing of gastric ulcer, several groups of cases have been published, showing this disappearance under different forms of medical treatment. There are certain errors of the niche which should be easily avoided by a careful radiographer—for example, a loop of small intestine may cast a shadow behind the stomach, or the rare condition of gastric diverticulum may simulate a niche; even calcareous glands along the vertical column have been mistaken for it. These conditions having been excluded, a niche is indicative, not only of a chronic ulcer, but also of the acute or subacute varieties, for I agree with the opinion expressed a little while ago by Barclay[8] on this subject. Disappearance of the niche in general means *healing of the ulcer. This must not, however, be taken* as an absolutely accurate statement, for filling up with granulation tissue and contraction of the ulcer may cause disappearance of the niche, although the base of the ulcer is uncovered by mucous membrane, and such a condition has been found at operation. On the other hand, I have had two cases operated on for persistence of the niche, and depressed scars only were found. Disappearance of the niche has been recorded in 71 and 91 per cent. of cases,[9] and its reappearance has also been noted.[10]

III. An Adequate Medical Treatment.

I shall now give a brief outline of an adequate medical treatment. It is one which I have been accustomed to employ for many years, but there are many other well-known methods, all no doubt fulfilling the required conditions equally well.

All the prevailing medical treatments aim at facilitating the emptying of the stomach and reducing the acidity of its contents, since delayed emptying and hyperchlorhydria prevent cicatrization,[11] and it is the correction of these disorders which brings about the healing of the ulcer.[12] As I have already indicated, the first object in treatment is to promote the healing of the ulcer in question, and the second to endeavour to prevent future ulceration.

A.—*To Heal the Ulcer.*

The disordered gastric functions are righted by diminishing the work of the stomach and affording it as much rest as possible. The patient is put to bed for an average period of four to six weeks, because the gastric functions are more easily restored in an organ at rest than when subjected to nervous and physical disturbances; and, the requirements of the body being less, the work of the stomach may be reduced by diminishing the quantity of food with less serious effects upon the general nutrition than when the patient is following his ordinary calling. When all symptoms have disappeared and two or three weeks have elapsed, the work of the stomach is gradually increased by adding to the food up to the full diet the patient is to live on subsequently. He then gets up and enters upon the ambulatory stage of his treatment. The diet should be one which calls forth the minimum quantity of gastric juice and which has the maximum combining power with hydrochloric acid. Finely disintegrated and non-irritating food, which passes easily through the pylorus, relieves pyloric spasm and reduces acidity; by facilitating the emptying of the stomach it reduces hypersecretion. The food to begin with should, of course, be liquid. Beef-tea and meat extracts should be particularly avoided, because they contain very little protein to combine with the acid; they excite a maximal flow of gastric juice, and have a low nutritive value. On the other hand, milk excites a much smaller flow and has a very good combining power with hydrochloric acid; my practice is to give it not only as a preliminary food, but throughout the treatment with each meal. In a straightforward case 7 oz. of citrated milk are given every three hours—at 7 a.m., 10 a.m., 1 p.m., 4 p.m., 7 p.m., and 10 p.m.—which diet the patient continues for a week. At the end of this time raw egg beaten up with milk (strength, one egg to half a pint of milk) is substituted for three of the milk feeds—namely, at 7 a.m., 1 p.m., and 7 p.m.—for another week or two. This is the diet for the first two or three weeks, the latter for preference; and now it is gradually built up at these times into three meals a day with three milk feeds alternating. This process takes another three weeks; thus:—*First week*: a thin slice of bread-and-butter is added to the three egg and milk feeds; the egg is lightly boiled; pounded fish (sole, plaice, whiting) substitutes one of the eggs; and, lastly, pounded chicken substitutes a second egg. *Second week*: a cereal such as arrowroot or ground rice boiled in milk, or custard, or junket, forms a second course to the fish and chicken; ordinary fish stewed in milk and ordinary chicken substitute the pounded foods; milk pudding with stewed apples or prunes (seived) form the second course. The patient may now commence getting up, but it is better to delay for another week. *Third week*: mashed potato and sieved greens are added; minced mutton and then ordinary mutton are given; the milk with meals is continued the whole time. The first meal is given at 8 a.m., and the 10 a.m. and 10 p.m. milk feeds are omitted, so that the patient is taking three meals a day at the ordinary times, and milk for his 4 p.m. meal. The diet is further increased up to a permanent one by the addition of other kinds of white fish, tender beef once a week, cold boiled bacon or ham, stewed lamb's tongue, calf's head, tripe, sweetbread, rabbit; a further variety in vegetables, omitting those of coarse fibre; an addition to the second course in the shape of pudding made with bread or sponge cake; and stewed fruit, except the sour varieties and those containing seeds or coarse fibre; he is on stale bread, dry toast, biscuits, rusks, and his cakes are best limited to sponge, rice, or madeira. Hitherto he has been drinking milk with each meal, and now he may have, if he wishes, coffee with milk, and weak tea, each once a day. A glass of water before breakfast and at bedtime is a good practice, and he must masticate thoroughly and be careful not to rush his meals, taking a little rest before and after each. Fried foods, soups and meat extracts, and preserved and salted or second-cooked meats, together with such condiments as pickles and so on, are to be avoided. His teeth are to be put in order, and all sources of ill health, such as septic foci, removed as far as possible.

Administration of Alkalis.

The administration of alkalis is a necessary part of the treatment of ulcer, because hyperchlorhydria is commonly present, and they should be given in the later stages of digestion.[13] My plan is to give magnesium oxide 10 grains and sodium bicarbonate 15 grains three times a day, two hours after the chief meals (that is, those at 7 a.m., 1 p.m., and 7 p.m.); and sodium bicarbonate 15 grains two hours after the intervening milk feeds (that is, those at 10 a.m., 4 p.m., and 10 p.m.). Calcium carbonate 10 grains is substituted wholly or in part for the magnesium oxide if the motions are too loose. The phosphates of calcium and magnesium have more recently been used as antacids. There is no danger of alkalosis, as in the unnecessary "intensive alkali treatment" of Sippy,[14] by their employment, but they are inferior to the alkalis I have mentioned in neutralizing power, which, given in the amounts I have prescribed even for long periods, produce no ill effects.

Belladonna.

Hypersecretion tends to subside like the other pathological processes with the above treatment, but it may be troublesome in the night, and here atropine is of value. Given before food, or in the early stages of digestion, atropine to some extent lessens the secretory response to food, but its chief use lies in its ability to relax the pyloric sphincter and thus bring down the acid curve by neutralization. It is not really necessary unless one is dealing with an obstinate case, and the mouth may become dry with the treatment. If, however, continuous hypersecretion is found to be present by the tube, and the acidity of the resting juice is high, atropine is to be given at bedtime in doses of 1/50 grain. It has been shown easily to limit this interdigestive hypersecretion, and herein lies its real value.

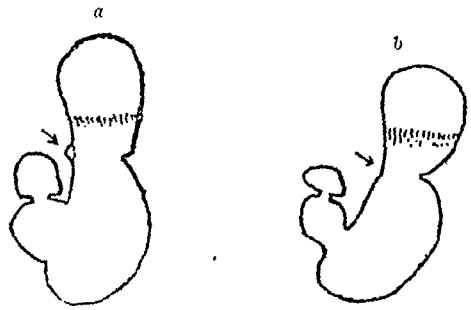

FIG. 1.—Drawings from radiograms of H. H. (female, 54 years of age). Ulcer on small curvature. (*a*) October 30th, 1929. Before treatment—ulcer niche. (*b*) December 18th, 1929. After treatment—ulcer niche disappeared.

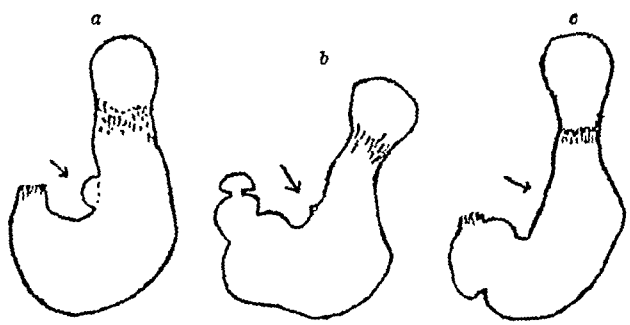

FIG. 2.—Drawings from radiograms of J. H. (male, 49 years of age). Ulcer on small curvature. (*a*) October 25th, 1929. Before treatment—large ulcer niche. (*b*) November 26th, 1929. During treatment—ulcer niche much smaller. (*c*) January 14th, 1930. After treatment—ulcer niche disappeared.

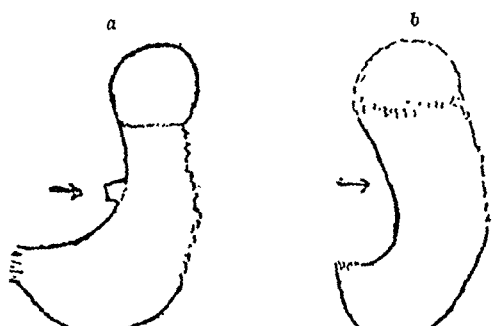

FIG. 3.—Drawings from radiograms of T. A. (male, 47 years of age). Ulcer on small curvature. (*a*) May 1st, 1929. Before treatment—large ulcer niche. (*b*) September 10th, 1929. After treatment—ulcer niche disappeared.

The treatment outlined above heals an ulcer quite well. Figs. 1, 2, and 3 are tracings of the *x*-ray appearances seen in three patients successfully treated in my wards at *University College Hospital within the last few months*, and which are shown by way of illustration. All observers find this, as I have already stated, to be quite a general rule; and, coincident with the disappearance of the crater, occult blood vanishes from the stools. Before freeing the patient these two tests, if they can possibly be applied, should be employed to prove that the ulcer is healed.

B.—TO PREVENT FUTURE ULCERATION.

The medical treatment having been administered and the general health restored, the patient is advised as to his habits and instructed to live permanently on the diet ordered. If he wishes to vary his diet he should see his medical attendant and ask his advice on the subject; and if any symptoms appear he is to get rid of them immediately by energetic treatment. He vanishes from our sight, and the subsequent course of events chiefly depends on himself. Some patients report their progress from time to time and scrupulously follow our advice, and, of these, recurrences occur in the old chronic cases only. The majority, however, doubtfully do so, and among these are most of the failures. When the patient is quite well many difficulties stand in his way. I need not enumerate these to you, who by your profession are students of human nature. All the manifold causes of dyspepsia gradually encroach; the lure of old habits and the exactions of business lead to forgetfulness in the healthy man, and an imperceptible return to the old manner of living. The position is summed up in the answer I received the other day from one of my old patients on inquiry as to his condition: "With a little self-denial I am in perfect health."

IV. THE PART PLAYED BY SURGERY.

A consideration of the above observations shows that medical treatment, efficiently applied, will heal the majority of ulcers; the intractable ones being those which are already too old and thickened, or have developed some complication when they come under the notice of the physician. In such cases, when medicine has failed, more drastic and more effective measures are obviously needed. The point at issue is when an uncomplicated chronic ulcer of the stomach or duodenum should be regarded as a fit case for surgical intervention, because there can be no question as to the surgical treatment of complications, except haemorrhage. This latter condition is not an indication for surgery, except, possibly, in rare cases.

It must be laid down quite definitely at the outset that *no case should be handed over to the surgeon unless it has been proved incurable by medical means*; and in making this statement I have the support of Moynihan[13] and other distinguished surgeons. I have described how a case should be treated, and an inquiry should first be directed to ascertain what medical treatment the patient has had, and what have been his subsequent instructions and conduct. I may, perhaps, here restate the observation already made that it is a matter for regret that so many cases are allowed to drag on for long periods of time without having had any systematic treatment for ulcer at all. If the patient has had satisfactory bed and ambulatory treatment the question arises as to whether he should be given further medical treatment or handed over to the surgeon. Every case must be judged separately on its merits, and the following points given due consideration: (1) the duration of the illness; (2) the length of the intervals of freedom from symptoms; (3) the length of time the patient has remained well since his treatment; (4) whether the recognized tests show that an ulcer is present. All these points are, of course, interdependent upon each other.

1. The duration of the illness is of the greatest importance, because, as we have seen, the older the ulcer the more difficult is the healing process. In a general sort of way it is a good rule to try further medical treatment if the duration of the illness has been no more than six or twelve months. If, on the other hand, the malady has been present for five years or more, it will be found, generally speaking, that an operation will be necessary. An onset with haemorrhage and attacks of haemorrhage at intervals are, of course, more reliable guides to the duration of the malady than pain. It is their significance as to the age and persistence of the ulcer which indicates operation, rather than the fear of further haemorrhage, because our aim is to heal *all ulcers whether they bleed* or not.

2. The length of the intervals of entire freedom from symptoms may indicate whether one is dealing with a single ulcer from start to finish, or with multiple recurring acute ulcers; for example, three or four years of complete freedom is commonly an indication of recurring ulcer,

whereas shorter intervals—say, six months—indicate a single ulcer. More significant of recurring acute ulcer are attacks of haemorrhage without pain—for example, if the haemorrhage has recurred at intervals of several years, with the total absence of symptoms in the intervals, the case should not be operated upon; whereas if pain has been present between the attacks of bleeding, it is probably one ulcer from start to finish, and the indication is towards operation.

3. A relapse within six or twelve months after the treatment would point more strongly to an operation than if relapse occurred after two and a half to three years.

4. No patient should be operated upon, even if there were clinical indications in favour of it, unless the presence of an ulcer is confirmed by the recognized tests.

These remarks are to be taken in a very general sort of way and as indicating how a case of relapse should be summed up. All these indications are, of course, subject to those obtained from the general condition of the patient and to his circumstances. For example, old people and those with some concomitant disease should not be subjected to operation unless the latter is absolutely necessary; and those in poor circumstances, and who cannot afford to give medicine a thorough trial, may prefer to take the shortest cut that affords a fair prospect of relief. Again, if, owing to the severity of the symptoms, wasting occurs from inability to take sufficient food, or anaemia from recurrent haemorrhages, operation is indicated.

V. Surgical Invalids.

It falls to the lot of the physician to see annually a certain number of unsuccessful operation cases, and he naturally wonders in each case whether the wisest course has been pursued in subjecting the patient to operation, and whether the most suitable operative procedure has been adopted. The particular operation selected must always be decided by the surgeon at the time of operation and determined by the conditions present, so that a variety of possible operations must always be available for use. There are definite principles, however, which should guide him in his selection, and which are based upon what we know of the pathology of peptic ulcer. We expect the surgeon not only to deal with the existing ulcer, but, in addition, so to alter the mechanism of the stomach as to ensure permanent achlorhydria and free emptying, so that immunity from future ulceration either of the stomach or the jejunum is assured. The first surgeon to insist upon reduction of acidity as being an essential to success was Paterson.[14] In order to protect the jejunum complete achlorhydria should be established by the operation, so that not only is the necrosing effect of hydrochloric acid eliminated, but also its action in activating pepsin.

The unaided stomach is not able materially to reduce the acidity of its contents, but this is normally kept in check by partial neutralization by regurgitation of the duodenal contents through the pylorus, the neutralizer being the pancreatic alkali—not the bile, as is sometimes erroneously stated. Pyloric spasm is commonly present in ulcer, and this condition prevents duodenal regurgitation, thereby maintaining a high acidity, especially if hypersecretion is present, and delays the emptying of the stomach. The surgeon alters this abnormal mechanism of the stomach by making a new outlet into the intestine, thus negativing this effect of the pylorus. With this end in view he either performs a simple gastro-enterostomy, or excises the pylorus together with varying portions of the stomach, anastomosing the intestine and stomach. Free emptying of the stomach is thus assured, and in many cases free regurgitation of intestinal contents into the stomach, thereby establishing the condition of achlorhydria. This desirable result is not, however, invariably attained, for, although the emptying may be satisfactory, in many cases regurgitation is defective, with the result that the acidity of the gastric contents remains as it was before the operation, or is only partially reduced. The patient thus runs the risk of jejunal ulcer, of a new gastric ulcer, or of his original ulcer remaining unhealed. This risk is small after partial gastrectomy, but is very real after gastro-enterostomy. The frequency of jejunal ulcer after gastro-enterostomy is not accurately known, because in addition to those ulcers which are operated upon there are acute ulcers which heal and recur, only revealing their presence by occasional bleeding, and ulcers in a later stage which cause pain and are very difficult to diagnose. It is particularly seen after the operation has been performed for duodenal ulcer, due no doubt in part, but not chiefly, to unrelieved hypersecretion, since the neutralization is a question of balance between acid and alkali.

In the absence of hydrochloric acid a stitch ulcer may no doubt arise, as in any other part of the body, but the occurrence of such an ulcer would be of relatively little importance. However high the percentage of successful gastro-enterostomies, we are still confronted with this fundamental inadequacy of the operation—that its power of permanently reducing the acidity of the gastric contents to the safety level is uncertain. This very materially detracts from the value of the operation, the ultimate result of which in any given case can never be accurately foretold. There is no mortality percentage in medical treatment, and if it fails the patient is no worse off. In addition to the mortality percentage of surgical treatment, if it is unsuccessful the lot of the patient is not uncommonly worse than before, and in some cases it is truly deplorable.[15] When a necessary operation is performed for an ulcer which has obstinately resisted medical treatment, the mortality percentage and complications of the operation may be put aside; but it is a different matter when it is performed for an ulcer which is easily curable by medical means, and the patient should not be subjected to it unless such means have been tried and proved a failure. There are therefore several problems which it is urgently necessary for the surgeon to solve.

Conclusions.

1. Gastric and duodenal ulcers are primarily medical diseases.

2. The majority of ulcers will heal by an adequate medical treatment, if it be thoroughly employed at a reasonably early stage of the malady.

3. The patient must for the rest of his life obey the dietetic and other rules laid down after he has been treated, otherwise he is liable to a relapse, especially if the treatment has not been employed at a comparatively early stage of the disease.

4. An uncomplicated ulcer should not be subjected to operation until it has been proved incurable by medical treatment.

5. If proved incurable by medical treatment, either as to the healing of the ulcer or the prevention of a recurrence, an operation is indicated with the reservations mentioned.

6. We expect surgery, in addition to healing or removing the ulcer, so to alter the gastric mechanism that recurrence is impossible; but since this result is at present uncertain, the gastric contents should be examined after every operation, and unless achlorhydria is established, the case should be handed back to the physician for medical treatment.

7. It is essential that greater attention should be paid by medicine to the treatment of dyspepsia and the early diagnosis of ulcer; when this malady is recognized an adequate medical treatment should be at once instituted.

HARE-LIP AND ITS TREATMENT.

BY

GILBERT B. WARBURTON, CH.M., F.R.C.S.,

SENIOR SURGEON TO THE ROYAL MANCHESTER CHILDREN'S HOSPITAL.

THIS paper is based on a considerable number of cases of hare-lip which have come under my care since early in 1920, when I was elected to the staff of the Royal Manchester Children's Hospital, and represents an attempt to set down such facts as I have been able to ascertain regarding the condition.

ETIOLOGY AND INCIDENCE.

As regards the cause, I have been able to find out very little except to confirm the fact that in a certain number of cases heredity plays a part. I regret that in the early cases I did not go fully into the family history, but for some years now I have carefully inquired of the parents as to whether any relatives have had a similar condition.

Out of 60 cases in which the history has been fully examined I have been able to trace a family history in 11. In only one of these 11 cases was it the parent—in this case the father—who had a hare-lip. More commonly it was an uncle or aunt or more distant relative who had been similarly afflicted. In two cases a relative had a cleft palate but not a hare-lip, and since the two conditions are so closely associated this is ranked as a family history. Of the 11 cases with family history the relative or relatives affected were on the father's side in 7 cases, and on the mother's in 4.

A certain number of mothers, when questioned, attributed the condition to a fright or shock during pregnancy. While somewhat sceptical about this, yet the more one inquires into these cases the less does one feel inclined to ignore the possibility of pre-natal impressions having an effect on the developing foetus. Shocks or impressions occurring in the later periods of pregnancy need not be considered, since the formation of the lip is completed at the eighth week of intrauterine life.

The histories of some of the cases where the mother has attributed the condition to a shock are perhaps worth mentioning.

1. In the case of a second child with no family history, the mother attributed the hare-lip to a fright at about two months caused by a dog jumping at her and banging her in the abdomen.

2. In the case of another second child with no family history, the mother told me that when she was between one and two months pregnant a man fell in a fit before her and cut his lip.

3. Hare-lip and cleft palate occurred in a first child, with a family history of cleft palate on the mother's side, but not of hare-lip. I am told that in the early months of pregnancy the mother worried a great deal in silence whether the baby would be born with hare-lip and cleft palate; when she was told that it had both she expressed no surprise.

I have heard of other cases where the mother has been quite convinced that her baby would be born with a hare-lip, and this has afterwards come about.

4. In the case of a second child with no family history, a cock jumped on the mother's neck at about two months, and pecked her.

5. In her first pregnancy another mother was constantly seeing two children with hare-lips who lived near to her. The child was born with a hare-lip, and there was no family history.

6. A second child was born to a woman whose brother had a hare-lip and cleft palate and died in infancy, but the mother did not remember him. All the time she was pregnant she was constantly meeting a baby with hare-lip, and could not get the thought of it out of her mind.

7. A third child with no significant family history was born with a cleft palate but no hare-lip. The other children were normal. In this child there was an incomplete cleft palate: before and during the mother's pregnancy with it she had a maid with an incomplete cleft palate which was not operated on. When the child was born it was found that it had about the same degree of cleft palate as the maid.

I am inclined to think that there must be a family history in many more cases than we can obtain it in. A considerable number of people get out of touch with their relatives, and know but little of their family histories.

In only one case have I met with two children in the same family with hare-lip. A second child with no family history had a left complete hare-lip and cleft palate, the first child having been normal. The third child was normal, but the fourth was born with a left incomplete hare-lip though with no cleft palate.

With reference to sex, the condition is much more common in males than in females. Out of 86 of my own cases which I have been able to trace 54 were in males and 32 in females. In this particular series of cases the proportions as regards sex are probably about the average, as I find that during the years 1922-28 inclusive there were admitted to the Royal Manchester Children's Hospital 253 patients with hare-lip, and of these 166 were males and 87 females. Both these groups of figures show that the condition is nearly twice as common in the male sex as in the female.

It is sometimes stated in textbooks that the condition is commonly associated with other congenital deformities, but, apart from its frequent association with cleft palate, this has not been my experience. Occasionally, however, we do find other deformities, such as talipes or naevi, and one of my cases of double hare-lip and cleft palate had at least six other congenital deformities; this, however, is quite exceptional.

My early impressions were that it was usually the first child of a family which was born with hare-lip, but on investigation this has proved to be erroneous, as out of 62 cases in which I have gone fully into this question I find that the condition was a little more common in the second child. The distribution of these 62 cases is as follows:

1st child	20	6th child	1
2nd "	23	7th "	1
3rd "	8	8th "	0
4th "	5	9th "	1
5th "	3		

We find the deformity to be much more common in the first two children, although occurring in any child in the family, but much less frequently in later children. At the same time we must remember that small families in many grades of society are more common than large ones, and, in addition, many parents having had a child born with a hare-lip or other deformity will purposely limit their family in case the other children should be brought into the world with a similar handicap.

The types met with have been the usual ones: *single incomplete*; single complete; double incomplete; *double complete*; double incomplete on one side, but *complete on the other side*.

I have had no case of median hare-lip; the condition is very much more common on the left side than on the right. A complete hare-lip is usually associated with a cleft palate, either a cleft in the alveolus or a complete cleft in the hard and soft palates. I have come across one case with a complete (double) hare-lip with prominent displaced premaxilla causing a cleft of the anterior end of the hard palate, but with the remaining portions of the hard and soft palate normally fused. This type is rare; there is a drawing of an infantile skull showing a similar condition in Berry and Legg's book on hare-lip and cleft palate (Fig. 13, p. 13).

In the incomplete varieties of hare-lip the deformity is usually not very severe and is generally easily remedied at operation. In some of the cases of double complete hare-lip the deformity is very marked; the central part of the lip and the premaxilla project forward in almost a horizontal direction from the tip of the nose, and this gives rise to what is little less than a hideous deformity.

TREATMENT.

Feeding and Pre-operative Details.

One of the main difficulties before operation is the question of feeding. In the severe cases the child is unable to suckle or to take food from a bottle, especially if there is an associated cleft palate, since the food regurgitates through the space in the lip or comes out through the nose. Some children can take food from a bottle when they have been unable to suckle from the breast, particularly if the bottle is fitted with a large-sized teat; many, however, cannot be so fed, and have to be fed with a spoon. The child is partially propped up and reclining on its side; it is then fed with a spoon into one of its cheeks. By this means the food is slowly swallowed, and the baby does not tend to regurgitate it.

The best food is the mother's milk drawn off and given with a spoon, when it can be utilized; for various reasons this can, however, rarely be done. Failing this, it is usual to give one of the reliable artificial foods or milk suitably prepared; it is my custom to keep a child on whatever food it has been accustomed to if it is thriving on it. Spoon feeding takes up a considerable amount of time, and is a tedious proceeding, but every effort should be made to get the child to gain in weight and to become fit for the operation, since an operation on a very debilitated child is likely to be fraught with disaster. Babies who are able to suckle at the breast should become accustomed to spoon feeding, as this will be the method used for at least several days after the operation.

It is my custom to operate on the lip before attempting to close the gap in the palate, and I usually defer the operation until the child is three months old. Some of the slighter cases can be operated on a little earlier if desired. At this age the child has generally a stronger hold on life; if it has been carefully fed it is in a much better condition to stand the operation—which in the worst cases is a severe one—than if it is operated on in the very early weeks of life. Moreover, the parts of the lip are a little larger and easier to handle.

Before the operation is performed the child should be in as perfect health as possible; it should be quite free from colds or cough, and as a general rule be steadily gaining in weight. There should have been no recent exposure to infection of any kind.

The best time of the year to operate is in the warmer weather of spring or summer; although one does operate on these cases in the winter, I certainly will not do so in very severe and particularly in foggy weather. It is advisable that the baby should be in the hospital or the nursing home for a few days to get accustomed to the new nurses, and vice versa. It is necessary to keep many of the children in hospital for a considerable period before operating, particularly those that come from poor and crowded homes. While waiting for the time of operation they are carefully fed, and every effort is made to get them to gain in weight.

If a child is steadily losing ground in spite of careful treatment, the operation is not likely to succeed or to help the child to pick up afterwards. Apart from the malformation many of these children are normal and bonny, but a certain number are puny and will not come on however much care is taken of them. If, in spite of careful attention and feeding, the baby is steadily going downhill, I do not think it wise to operate, as I am convinced that merely closing the lip will not make any material difference to the general well-being of the infant except in very rare cases. A few babies never become fit for operation, and gradually waste away or die of some intercurrent malady in spite of all treatment; these are, however, in my experience, few. I do not hesitate to postpone the operation if the child does not seem up to its normal condition, since it may be sickening for some illness. With attention to these pre-operative details the results are much more likely to be successful than if the operation is undertaken without preliminary care.

Operation.

The operation I have employed in practically all my cases commenced as a modification of that which is usually described as Rose's, but which has been gradually altered. This procedure, varied a little in different patients, has enabled me to bring the parts of the lip together in all types of hare-lip that I have met with. I will mention *briefly what I consider to be the most important points.*

If possible the anaesthetist and surgeon should be accustomed to working together and to know each other's methods, for the anaesthetics are not easy to give. I have to thank Dr. K. B. Pinson for anaesthetizing the majority of these patients for me.

The child is anaesthetized first with ether or a mixture; this is later changed over to chloroform given by means of a Junker's inhaler. The anaesthesia, while not being very deep, *should be sufficient to keep the child perfectly* still and free from movement; lightness of anaesthesia and any straining or struggling tend to increase the bleeding and to shock the patient. I prefer to have the child lying flat, with the head slightly overhanging the end of the table and supported on a rest, the surgeon standing behind. A thread stitch is placed through the tongue to control it, and to make any necessary sponging-out of the pharynx easier.

The lip is everted, and the reflection of mucous membrane is divided where it meets the alveolar margin; the soft parts of the face are then loosened from the underlying bone outwards and upwards for a considerable distance, chiefly by means of blunt dissection, and all the time keeping close to the bone. The ala nasi must also be separated from the bone, especially in cases where it is very flattened. The undercutting is necessary more on the outer than on the mesial side, and the amount required depends on the width of separation of the parts of the lip. Bleeding at this stage can usually be readily stopped by means of pressure with gauze pads; when one side has been loosened a pad can be packed under it while the other side is being freed. A certain amount of blood usually finds its way into the pharynx and will require to be sponged out; this should be done with the utmost gentleness, so as not to irritate the pharynx or shock the patient. The freeing of the parts of the lip is continued on both sides until they are so thoroughly mobilized that they can be brought together without any tension.

The next step consists in paring the edges of the lip and shaping the flaps so that two equalized raw edges may come together. The knife is inserted at the junction of the red margin and the skin in the cleft, and the red margin is excised, sacrificing as little of the true skin as possible. When the vermilion border of the lip is reached a very short horizontal cut is made between the skin and the border so as to turn down a little flap, which is then shaped up. This is next done on the other side, taking care to get both sides equal in length. The freshening of the edges should run well into the nostril, since in closing this it is advisable to make it less than it would be normally, for invariably some dilatation takes place after the operation.

In many cases of incomplete hare-lip we find the corresponding nostril unduly large, owing to the fact that although the skin has partially fused the deeper portions of the lip have not done so. In these it is necessary to carry the incisions into the nostril, first converting the incomplete hare-lip into a complete one; when the subsequent stitching up is done the nostril is made smaller and more shapely. When the edges of the lip are pared there is sharp haemorrhage from the coronary arteries; this is checked by Smith's clamps.

The suturing is next commenced; one stitch of fine silkworm-gut is placed in the free edges of the lip and held by Spencer Wells forceps, but not tied. The next one is placed at the upper end to shape and partly close the nostril. The third stitch is put in at the junction of the red margin of the lip with the skin, as it is most important to see that this line comes into accurate apposition on both sides. About two more silkworm-gut stitches are passed deeply into both sides of the lip and held in forceps. When all of the sutures have been placed the one at the free edge is tied; next the upper one at the margin of the nostril; thirdly, the one apposing the red margin; and finally those in between, bringing the edges into apposition. One or two fine horse-hair sutures may be required superficially to secure accurate skin approximation. A few catgut stitches are put in on the inner side of the lip, traction on the lowest suture causing its eversion and enabling these to be put in. These sutures, in addition to helping to close the gap in the lip, prevent food from getting into it and also, by restoring the continuity of the mucous membrane, prevent any fusing of the inner side of the lip with the areolar margin, thus finally leaving a free and mobile lip.

The foregoing description applies chiefly to unilateral cases, but in those of double complete hare-lip there is the further complication of the protruding pre-maxilla, which may stick out like a proboscis. I do not think the premaxilla should ever be removed, and personally have never excised it. In cases where it has been taken away there is marked flattening of the upper lip and narrowing from side to side.

In double complete hare-lip the central portion of the lip is separated by dissection from the underlying bone, and if the pre-maxilla is very prominent it is gently forced back by pressure so as to lie between the maxillae. The edges of the central portion of the lip are pared until it is V-shaped. All the red margin is removed, as no attempt is made to incorporate it in the edge of the newly constructed lip; it is finally placed between the outer parts of the lip, and the point of the "V" lies somewhere about half-way up the lip. In double complete hare-lip the lateral parts have to be very widely mobilized so as to bring them across the pre-maxilla without undue tension. The steady pressure of the newly united lip gradually forces the pre-maxilla backwards.

In all cases the lip is, if possible, made a little longer from above downwards than one wishes it to be finally, since a certain amount of contraction in the scar and subsequent shortening will take place. It is often wise to allow a little protrusion of the red margin almost in the form of a papilla to be present when the operation is completed, as this will later contract, and tends to prevent the notching of the lip which is sometimes seen.

When the operation is completed the parts are cleansed, and either dusted with dry boric powder or lightly painted over with tincture of iodine, no dressing being applied.

Post-operative Treatment.

After the operation the child is kept warm and out of draughts, and every effort is made to prevent it from getting "chesty," or catching a cold and developing a cough. It should be prevented from crying if possible, since this would make the stitches tend to cut into the lip. Usually a small dose of nepenthe is necessary when the child is coming round from the anaesthetic, and the elbows are splinted to prevent the hands being applied to the mouth. There is usually a post-operative rise of temperature to 100°, or it may go higher to 101° or 102°; usually this rapidly subsides and comes down to normal. Feeding after the operation is by means of a spoon, and the lip is kept dry and clean.

In the majority of cases healing is complete in about seven days from the operation; the sutures are taken out, some on the fifth day, and the remainder about seven days after the operation. In only one of my cases, and this an early one, did the lip break down almost completely. The child had a complete double hare-lip, and at the operation the flaps were tight and came together under tension; as the sutures were cutting into the lip they were removed in a few days by the ward sister. The left side held, but the right side gave way. A second operation six months later was again unsuccessful, and before another attempt could be made the infant developed some chest condition, probably pneumonia, at home, and died.

The scar at first is distinct, but as time goes on it becomes whiter and much less noticeable.

Altogether I have performed the operation on 82 patients, including two who had been operated on elsewhere. In one there was a complete single hare-lip which had broken down from end to end; the other had a right incomplete and left complete hare-lip and had been operated on twice previously; a very small portion of the right side was holding, the left having broken down completely. In this case there was a very wide gap in the lip, and very little tissue left to work with. By means of extensive undercutting I was able to get the parts together, and firm union followed both in this and in the previous case.

MORTALITY.

In this series I have had five post-operative deaths; I consider this death rate too high. There is sure to be a certain death rate, since a fairly severe operation is being inflicted on a very young child, and, however careful we may be, some of these infants will develop post-operative pneumonia.

The deaths were as follows, and, as will be seen, two occurred in my very early cases.

1. A bad double complete hare-lip and the sixth case in the series; operation July 6th, 1921. The patient died on the operating table just as the operation was completed. Probably the operation took a long time, and towards its termination the child became pale and died of heart failure in spite of attempts to resuscitate it. This death I regard as purely due to operative shock.

2. Double hare-lip; operation September 21st, 1921. At the termination of the operation the patient was noticed to have collapsed. He recovered for a time, but two days later died of heart failure. A post-mortem examination revealed a patent foramen ovale in the heart, and so death at an early age was inevitable.

3. Left incomplete hare-lip; operation on May 10th, 1922. The patient survived the operation, and was well for several days, unfortunately she then developed enteritis, and died nine days after the operation from this cause.

4. Left complete hare-lip; operation on April 16th, 1927. The infant afterwards developed broncho-pneumonia, and died in three days.

5. Right incomplete hare-lip; operation February 9th, 1929. A spell of very severe weather set in after the operation; the child developed pneumonia four days later, and died two days afterwards.

The last 59 cases have been operated on with only two deaths, both from broncho-pneumonia. This shows a distinct improvement on the earlier series, and with more experience in operative technique and after-treatment a further improvement may be expected.

Points which have particularly interested me in looking over these cases have been:

1. The great preponderance of the condition in males.

2. The fact that, in the cases which have come under my care, it is most common in the second child.

3. The great rarity of more than one child in a family being affected.

4. The distinct tendency in a considerable percentage to run in families. My personal view is that if the family history could be more fully investigated we should find a history in a larger number than at first appears to be the case. It is curious that it is so rarely one of the parents who has had a similar condition, but more often an aunt or uncle, or more distant relation.

5. The possibility of the effects of pre-natal impressions in the first few months on the developing foetus. Personally, I feel forced to the conclusion that there must be something in this. There may be, in addition, a germ history, but I am inclined to think that any prejudice about this particular deformity on the part of the mother or coming into constant contact with others who have it may influence the foetus in its earliest stages.

EXCRETION UROGRAPHY.

*A Preliminary Note on a New Method of Radiological Demonstration of the Urinary Tract.**

BY

KENNETH HERITAGE, M.B., B.S., F.R.C.S.Eng.,

RESIDENT MEDICAL OFFICER, MILLER GENERAL HOSPITAL.

AND

R. OGIER WARD, M.Ch.Oxon., F.R.C.S.Eng.,

SURGEON IN CHARGE OF GENITO-URINARY DEPARTMENT, MILLER GENERAL HOSPITAL.

(With Special Plate.)

THE radiological demonstration of the hollow viscera by filling the lumen with opaque medium is a method that has found wide application in surgery; in fact, it can be assumed that there are few cavities or potential cavities which remain beyond the scope of this method of examination. Taken collectively, the accepted methods fall into two main groups. First, the artificial filling of the lumen with a radiographically demonstrable medium introduced from without, frequently under a small head of pressure. This is seen in the present method of pyelography via the ureteric catheter, which has marked so great an advance in renal diagnosis. The second group depends on the production of a radio-opaque secretion to demonstrate the excretory passages of the gland. While imposing very definite limitations in application, and difficulty in finding a suitable non-toxic yet selective excretory substance, this method offers an advantage in showing a picture naturally by instrumentation. Graham's epoch-making work in cholecy-stography, employing an organic combination of a cholagogue (phenolphthalein) with a radio-opaque [illegible]

*Submitted for publication on March 3rd, 1930.

has demonstrated the possibility of this method, and whilst superficially it would appear that the urinary tract offers an obvious field for the application of this method, only recently have attempts in this direction been attended with any measure of success. Probably the satisfactory results which have attended the transvesical method in the majority of cases have discouraged the pursuit of an excretion method.

The earlier work on this subject is associated with the name of Roseno.[1] Attempts had been made by Osborne, Sutherland, Rowntree, and Scholl[2] in 1923, using the oral administration of 20 grams of sodium iodide. Satisfactory cystograms alone were obtained. Rosenstein and von Lichtenstein[3] obtained, in only a few cases, with the help of pneumo-radiography, an exact picture of the kidney pelvis. Also the attempts of Volkmann and Hrynt-chaks[4] were unsatisfactory. The latter worked with not less than fifty preparations, and made 150 animal experiments. The problem remained thus until Roseno conceived the idea of combining intravenous administration of sodium iodide and urea with subsequent radiology of the urinary tract. After preliminary experiments on dogs, the dosage and time of exposure were established, and pyelographic pictures were obtained in a series of eighty cases.[5] The dose required was large. Roseno used the iodide equivalent of 38 grams of iodine, and while we are aware that equally large doses have been used intravenously in the treatment of syphilitic conditions,[6] an iodide idiosyncrasy must be very carefully excluded. Repeating Roseno's method, we were able to obtain a faint yet definite delineation of the urinary pelves and ureters; the generalized tingling, slight headache, and constitutional reaction occasionally associated with the injection, however, do not recommend the method as a routine procedure. Still, quite serviceable pictures can be obtained by this method, especially in those cases where an obstructive lesion delays emptying of the renal pelvis. Roseno claims that the test has value as an indication of renal function: normally secreting renal tissue will give an early dense shadow, while one with poor function will give a faint shadow late, or none at all. To avoid the disadvantages of the intravenous method Ziegler and Köhler,[7] following up the earlier work of Rosenstein and von Lichtenstein,[3] gave sodium iodide and urea (10 grams of each in milk) by the mouth, and obtained pyelographic pictures at various times up to four hours, after half an hour's compression of the desired ureter with an abdominal pad. Our results from this method in a small number of cases (six) were not satisfactory, although, with good radiography and a thin patient, the outline of the renal pelvis and calyces could be obtained. The compression was not without objection, both to the patient and in obviating one of the advantages of the excretion method—namely, the value of obtaining a view of untouched urinary tract.

Recently the difficulties which surround excretion pyelography have been considerably cleared by the work of Swick,[8] Binz, and Raeth. The observers attempted to obtain an outline of the gall-bladder after intravenous administration of selectan-neutral (an iodo-pyridine). The gall-bladder failed to show, but the kidney shadow came out so well that further work was devoted to this end. Selectan-neutral proved uncertain, and, as nausea, vomiting, and headache so often followed its use, a more innocuous compound was sought. Sodium-glycin was introduced in place of a methyl group, and "uro-selectan"* was obtained.

This preparation has proved satisfactory. It is harmless even in large quantities (3 grams per kilo of body weight is tolerated by the guinea-pig); it is soluble up to 50 per cent.; it contains 42 per cent. iodine in organic combination, and is excreted unchanged from the kidneys in sufficient concentration to give good radiographic shadows in fact, it can be almost completely (95 per cent.) recovered from the urine. We have recently had the opportunity of testing this substance clinically, and recognize in it a very valuable method, both in the elucidation of the clinical case and in the new field which it opens out for the investigation of the pathological anatomy of the upper urinary tract.

*This drug will shortly be procurable in this country.

Technique.

The technique is as follows. The dry greyish-white powder is dissolved in 100 c.cm. of warm distilled water, the solution filtered twice and sterilized in a water-bath for twenty minutes. A deep reddish-brown clear solution results, which, after cooling, is ready for intravenous injection. For an adult male, 40 grams of uroselectan form a satisfactory and easily tolerated dose. This allows 0.65 gram per kilo of body weight, and although much more than this can be given without ill effect, we find that this scale gives satisfactory results. An iodide idiosyncrasy is sought beforehand by the administration of potassium iodide, and by painting a portion of the skin with iodine on the day before injection. The solution can be given through a single puncture into the median basilic vein by means of a large Record syringe (50 c.cm.), and although we have not always been successful in preventing slight leakage into the tissues at the point of puncture, no ill effects of this accident have been noted beyond a little local irritation and tingling. No thrombosis followed injection. In this respect it differs markedly from experiences with the intravenous administration of tetraiodo-phenolphthalein. Following injection, generalized tingling may be noted, but frequently no abnormal sensations are recorded by the patient.

Injection is best carried out on the *x*-ray table, and the first picture taken five to ten minutes later. So far the best results have been obtained by using 15 × 12 films, with the Potter-Bucky diaphragm, but with no compression, using ten seconds' exposure. By this means a view of the whole tract is obtained, and a valuable comparison is obtained between the two kidneys. Pictures are taken at half an hour, one hour, and two hours from the time of the injection, the bladder being emptied just before each exposure in order that its shadow may not obscure the lower part of the ureter. If the renal function is normal, a shadow of the whole excretory urinary tract is obtained half an hour after injection, and is maintained for several hours. If the renal function is subnormal, a corresponding loss in density of the shadow is noted. In severe degree of renal impairment a shadow is only obtained after six to twenty-four hours or not at all. If the renal shadow is absent, then either no kidney is present on that side, or it is inactive, or very severely damaged by disease. Such results are seen in pyonephrosis, advanced renal tumour, or in long-obstructed infected kidneys. Findings of this character demand further cysto-scopic elucidation. Yielding as it does so comprehensive a grasp of the urinary condition present both functional and anatomical, we believe that excretion urography will come to occupy a prominent position in urological investigation.

Indications.

More and more in urological work does the need to [illegible] routine pyelography obtrude itself. Just as cystoscopy has risen from an occasional procedure to an essential part of routine urology, so we are coming to [illegible] more frequent employment of pyelography as [illegible] to gain a complete knowledge of each [illegible] the surgeon often feels that there is a double [illegible] bladder with its [illegible] in his hands.

It is fortunate that, at this point, a method is put forward which not only promises to give at a glance a view of the excretory passages in their physiological state, but which also may be of value as an index of differential renal efficiency. It is to be expected that in a large number of cases excretion urography will be performed before the patient objects to cystoscopy or pyelography by the instrumental method. More cogent indications are impassible obstruction of the urethra or of the ureters, severe haemorrhage, multiple urinary fistulae, "thimble bladder," in the case of small children, or in cases of implantation of the ureters into the bowel. In prostatic hypertrophy with intravesical projection rendering ureteric catheterization both difficult and inadvisable the intravenous method will also find a place.

Contraindications.

Cystoscopic pyelography will still remain the method of choice in the investigation of mild haematuria where the origin of the haemorrhage must be sought, and a distension pyelogram obtained, to exclude early renal neoplasm.

Another contraindication to intravenous pyelography will be advanced renal destruction, with either latent or manifest uraemia. The only death following this method occurred in a girl, aged 10, who had bilateral renal insufficiency from pyelonephritis, and a blood urea of 92 mg. per cent. before the injection.[7] Iodine idiosyncrasy and hyperthyroidism are contraindications, as also is acute inflammatory renal disease.

We have used this method on a series of patients suffering from varying degrees of urologic disease, typical examples of which are here instanced. We regard the exclusion of latent uraemia by blood urea examination as an important preliminary. None of our patients has shown the slightest reaction following the injection. The urine has been examined at intervals following the test. No evidence of irritation of the urinary tract has been found, and, although it has been used in chronic inflammatory disease, no increase in pus cell or albumin content has been noted. No increased frequency or pain on micturition has been present in our cases. A constant feature has been the raising of the specific gravity of the urine during the time of excretion; this often rises to 1040. Von Lichtenberg and Swick[8] suggest that this fact may be used as a test of renal function. Further work, however, is required on this point.

Conclusions.

1. A method of *urography is described* whereby a picture is obtained of *the whole* urinary tract without instrumentation, *provided both* kidneys retain in some degree their excretory function.

2. This method also offers a differential test of renal function.

3. The procedure is harmless; over 200 cases have been recorded without any disagreeable sequels.

4. The results are easily obtained, and of good quality, leaving in most cases no doubt as to the condition present.

5. The method is advocated as one of real value in routine urology, provided certain contraindications are observed.

6. The method promises to be of great value in elucidating the pathology of surgical disease of the kidney, especially hydronephrosis. Further work is indicated in this direction.

CLINICAL NOTES.

Our first attempts at excretion pyelography were carried out in November, 1929, and although the shadows obtained of the renal pelves were sufficient to be of some clinical value, they were too faint to bear reproduction. It was only when uroselectan became available and was employed that pyelograms capable of reproduction were obtained. The following cases and the accompanying pictures (see Special Plate) therefore illustrate the use of this drug, which we have employed in seventeen cases.

CASE 1.

A man, aged 43, complained of fixed pain in the left loin. No urinary symptoms were present. The urine was normal to chemical and microscopical examination. He was given 40 grams of uroselectan, dissolved in 100 c.cm. of water, intravenously. No abnormal sensations were experienced by the patient, beyond a feeling of heat immediately after the injection. The first radiogram, taken ten minutes later, shows a normal left renal outline with the renal pelvis lightly outlined by the drug. Nicely cupped calyces could be seen. The right pelvis showed the early overfilling which Roseno[7] describes as probably due to the diuretic effect of the drug. Fig. 1 shows the appearance at the end of a quarter of an hour. Further pictures were taken after half an hour, one hour, and two hours, and show the drug being excreted in considerable quantity at each of these times. The urine was examined microscopically before the test, and thirty and sixty minutes after the injection. It was quite clear to macroscopic examination, and on no occasion was anything pathological found. The urine remained acid throughout, and rose to a maximum specific gravity of 1034 half an hour after the injection. No urinary symptoms followed the examination, and the patient remained ambulatory throughout. We regard the evidence in this case as sufficient to exclude any renal source of pain.

CASE 2.

A woman, aged 27, complained of attacks of left renal pain, with pyrexia, since October, 1928; also of frequency of micturition—by day hourly, by night twice. The urine was acid, specific gravity 1010; trace of albumin; pus and epithelial and red blood cells present on microscopic examination. Culture shows a moderate growth of *Bacillus coli*. Cystoscopy shows oedema of both ureteric orifices. Indigo-carmine: right efflux good concentration in six minutes; left orifice gives no colour in eight minutes, and only a very poor colour in seventeen minutes through a ureteric catheter. Urine obtained from the left ureter shows the same findings as above, with a urea content of 1 per cent. under fasting conditions. She was given 40 grams of uroselectan, dissolved in 100 c.cm. of distilled water, intravenously. The radiogram taken eight minutes later shows a hydronephrotic left pelvis with distension of the calyces, and a normal right pelvis and ureter. The left ureter did not appear. Fig. 2 shows the appearance a quarter of an hour after the injection. Pictures taken after half an hour, one hour, and two hours show progressive fading of the shadows of the right pelvis and ureter, while the left pelvis remains opaque and clearly shown throughout. At no time was the left ureter seen. Urine, obtained 45 minutes after administration of the drug, was acid; sp. gr. 1038; trace of albumin. Pus cells, epithelial cells, and red blood cells were present as before, but not in increased numbers.

The early appearance of pelvic shadows seems to indicate the presence of satisfactory secreting renal tissue on both sides, while the prolonged retention of the drug in the left pelvis, with early hydronephrotic appearance, suggests obstruction at the pelvi-ureteric junction. On the strength of the above findings we propose exploring the left kidney with a view to performing a plastic operation.

CASE 3.

A woman, aged 26, was quite well until August, 1929; then she had a severe attack of haematuria which lasted two days. There has been gradual loss of appetite and weight since. Recently she has had pain on micturition, and marked frequency by day and night, with pain in the left renal region. Examination showed an anaemic spare woman. Both kidneys were palpable, not lobulated or tender, the left somewhat larger than the right. The left ureter was palpable crossing the left iliac fossa.

X-ray examination showed an enlarged left renal shadow only. The urine was acid, and contained a cloud of albumin and pus cells, epithelial cells, and occasional red blood cells. Culture showed a scanty growth of *Streptococcus faecalis* and coliform bacilli. The specific gravity was 1006. Tubercle bacilli were present in a twenty-four-hour specimen. Blood urea 40 mg. Cystoscopy showed a contracted bladder (capacity 4 oz.), and this, combined with acute cystitis, rendered a view difficult. The ureteric orifices were retracted and displaced; the mouths of two diverticula were seen above the right. A ureteric catheter could not be introduced into either orifice. No indigo-carmine was seen in twenty-five minutes, although slight staining of the urine appeared later. An intravenous injection of 40 grams of uroselectan was given, and was followed by no ill effects beyond tingling and a feeling of heat. X-ray examination a quarter of an hour later showed very marked dilatation of the whole of the left ureter, slight dilatation of the renal pelvis, and loss of cupping of the calyces. The shadow was good, even at this early time. No pelvis or ureter was seen on the right side. Films were taken at half an hour, one hour, two hours, four hours, and twenty-four hours. The drug was seen outlining the left renal pelvis and ureter in each of these films in diminishing density, but at no time was any seen on the right side. Fig. 3 shows the film taken at one hour. Urine examined after the investigation showed no increase in the leucocyte or red cell content, and the specific gravity during the test rose only to 1016.

The above evidence suggests an obstruction to the lower end of the left ureter, with hydro-ureter and early hydronephrosis, while the right kidney appears to have a very low excretory function probably due to extensive tuberculous disease. Contrary to what one would have expected on clinical grounds, the left kidney is the more active organ, as shown by the early appearance of the drug on this side. We propose exploring the lower end of the left ureter with a view to dilatation of the vesical orifice, and ascertaining if the left kidney remains uninfected.*

*This has been done. The left ureter was explored, and found to be grossly dilated; failing to obtain urine by aspiration, the ureter was incised to admit a ureteric catheter. Indigo-carmine appeared here in five minutes, and tubercle bacilli and pus cells were found in the urine collected. The patient died twelve days later. Dr. H. F. Brewer, Pathologist to the hospital, makes the following report: "Autopsy shows death from generalized tuberculosis. *Kidneys*: the right was entirely destroyed, and consisted of a number of closed areas containing caseous material. The left in its upper pole had a circular caseous area about one inch in diameter, which was in communication with the pelvis of the left ureter. The remainder of this kidney, except for congestion, appeared normal. Sections of the functioning kidney tissue were natural except for hyperaemia and some slight cloudy swelling of the epithelial cells of the tubules. The glomeruli were normal. The urine in the bladder at the post-mortem examination showed no increase in pus or red blood cells as compared with the findings a month previous to death. No casts were present. The post-mortem examination indicates that the remaining functioning renal tissue has suffered no acute damage from the use of uroselectan."

CASE 4.

A boy, aged 17. Sudden onset in July, 1929, of left renal pain, with temperature 101°. Albumin, blood, and pus were present in the urine. Culture showed staphylococci. Blood urea 23 mg. The urine from the right ureter was normal; that from the left contained pus cells. No tubercle bacilli were seen. The bladder was normal. Indigo-carmine—good concentration from the right in five minutes; none seen from the left in twenty minutes. He was given 40 grams of uroselectan intravenously. Half an hour later a definite picture of the right renal pelvis and calyces was obtained. Fig. 4 shows the appearance after one hour. Exposures were taken at one hour, two hours, and four hours; at no time was any shadow seen on the left side. Cystoscopic pyelography showed a large pyonephrosis on the left side, completely replacing the renal tissue. Fig. 4 agrees very closely with a right pyelogram obtained by the cystoscopic method. It is significant that the uninfected side excreted the drug after half an hour in sufficient quantity to give a shadow, while the infected side failed to show a shadow in any of the radiograms, thus illustrating the depressing effect of sepsis on the renal function.

CASE 5.

A man, aged 28, who for three years has suffered from right renal colic. No frequency; never haematuria. Examination shows tenderness in the right loin only. The urine is straw-coloured, acid, and the specific gravity is 1012; albumin is present. Microscopic examination showed a few pus cells and red blood cells. Cultures were sterile. Blood urea was 31.5 mg. per cent. X-ray examination showed a pyriform oxalate calculus in the right renal pelvis.

After the usual radiological preparation, 40 grams of uroselectan were injected intravenously. Fig. 5 shows the condition a quarter of an hour later. The left renal pelvis and renal outline are shown clearly to be normal. The right pelvis is hydronephrotic, and in the negative the calculus is seen lying within the shadow of the pelvis. The depth of renal tissue and the early appearance of the drug in the right pelvis indicate that the stone has so far caused little interference with excretory function. Pyelolithotomy confirmed the above findings. During the excretion of the drug the specific gravity of the urine rose to 1035, but subsequent examination showed no change in the abnormal constituents already present.

The advantage, in the cases of uninfected calculi, of obtaining all the necessary evidence without recourse to instrumentation, is self-evident.

CASE 6.

A man, aged 30, who had recently undergone excision of a urethral stricture. The cystoscope could not be passed owing to a fold. There was no obstruction to micturition. Intravenous pyelography showed normal renal pelves half an hour after the administration of the drug.

CASE 7.

This patient had nephrostomy performed in October, 1929, for infected right hydronephrosis and incipient uraemia, the left kidney being congenitally undeveloped. The left kidney excreted only two to three ounces per diem, and concentrated urea only to 0.4 per cent. Nephrostomy reduced the blood urea from 95 mg. per cent. to 44 mg. per cent. A ureteric catheter could not be passed into the right pelvis from the ureter, and a satisfactory pyelogram was not obtained via the nephrostomy tube. The patient was given 40 grams of uroselectan intravenously. An irregular ill-defined shadow began to appear after half an hour, and was more intense in two hours, but no shadow was seen on the left side. Unfortunately the patient (who was an outpatient) could not stay for further x-ray examination.

CASE 8.

A boy, aged 7, who for twelve months has had attacks of symptomless haematuria. Cystoscopy shows no vesical cause for the haematuria. Indigo-carmine—good colour from right in five minutes, poor from left in fifteen. The urine collected from each ureter contains many red blood cells with epithelial cells. A few red blood cell casts were occasionally seen. X-ray examination was negative. Blood urea was 45 mg. per cent. The blood count shows very marked eosinophilia (23 per cent.). A blood Wassermann test was positive (++); the father's Wassermann reaction was also positive (++). The stools and urine showed no evidence of paracytic cysts or ova. The condition is considered to be one of chronic syphilitic nephritis, as cystoscopic pyelograms show no abnormality. The patient was given 16 grams of uroselectan in 40 c.cm. of distilled water. A film taken a quarter of an hour later shows a little drug in the bladder only. A film at twenty-five minutes shows the right pelvis outlined, whilst the left pelvis began to show only after an hour. The right pelvis still showed faintly after four hours. The findings were similar to those obtained by cystoscopic methods.

Two normal patients were used as controls—one a youth aged 19, the other a boy aged 12. In each case the pelves were seen after fifteen minutes.

CASE 9.

Fig. 6 shows the result obtained after thirty minutes in a woman, aged 23, whose right ureter has been transplanted into the rectum for epispadias, with vesical incontinence.

In conclusion we wish to express our thanks to Dr. Wylie, radiologist to the hospital, for the use of his department, and to Miss Kreckeler, our radiographer, for her very able co-operation. We would also like to thank Dr. H. V. Morlock, assistant physician to the hospital, for his helpful interest and advice.

THE HINGED BONE-GRAFT.

BY

ARNOLD K. HENRY, M.B., B.CH.DUBL., F.R.C.S.I.,

PROFESSOR OF CLINICAL SURGERY, FACULTY OF MEDICINE, CAIRO, AND DIRECTOR OF THE SURGICAL UNIT, KASR-EL-AINI HOSPITAL, CAIRO.

(With Special Plate.)

THREE years ago I described in this *Journal* a method of splinting unstable feet by means of hinged grafts, which combined stability with a degree of useful movement.[1] The results have been so entirely satisfactory that a further description is desirable.

The grafts are made from osteo-periosteal strips implanted into bony grooves, cut in the back of each malleolus, and extending on either side of the foot to a point just beyond the mid-tarsal articulation. Connivance during convalescence at slight movements of plantar flexion and dorsiflexion of the foot secures the formation of a hinge in each graft just distal to the tip of the malleolus. An internal living splint—like the hinged cage-splint used externally for loose knees—is thus incorporated with the ankle.

I have employed the method in two kinds of case: (1) for patients with calcaneo-valgus deformity due to paralysis; (2) for complete foot-drop or "dangle-foot." Before grafting, any fixed deformity in the paralysed foot must, of course, be corrected by manipulation or tenotomy.

Paralytic Calcaneo-valgus Deformity.

Apart from hinge-grafting, the operations devised to cure this deformity have either failed to stand the test of time or have spoilt the shapeliness of the part. A tenodesis will stretch; transplanted tendons are inadequate, and astragalectomies make malovely ankles. Fig. 1 is an x-ray picture of a foot hinge-grafted two and a half years previously for an extreme calcaneo-valgus deformity. The girl, when shown in the Surgical Section of the Congress held during the centenary celebrations of the Cairo School of Medicine, could stand and hop on the grafted foot, and could move it in a vertical plane. There was no lateral instability of any kind. (One of the two hinges is clearly seen in the radiograph.) A second patient was operated on shortly after the first, with a satisfactory result.*

"*Dangle-foot.*"

Many operations have been devised for this disabling condition. Some are unsatisfactory; Jones and Lovett regard arthrodesis as a method "to which at best but an

* A third patient, but with an associated fixed deformity, has recently been hinge-grafted after correcting the fixed equinus component by tenotomy.

imperfect functional result," and "contraindicated in young children." The end-results, too, of tenodesis that I have seen have been mediocre, while other procedures are either mutilating or less simple of performance than the operation of hinge-grafting.

Makers of artificial limbs realize the disadvantage of a foot fixed immovably to the leg, and they provide limbs with a slight degree of movement at the ankle-joint. I believe that some mobility is equally desirable in the living foot, and that while bony fixation at right ankles to the leg is good, a stable foot with a few degrees of movement in the vertical plane is better. This can easily be got, in the most unstable feet, by means of hinged grafts.

Figs. 2*a* and 2*b* show *x*-ray pictures of a foot hinge-grafted fourteen months ago; the whole lower limb was paralysed by a stab wound of the cauda equina. The foot is at a right angle to the leg, and the hinge grafts give a range of about 5 degrees of movement in the vertical plane, which allows the leg to rock naturally on the foot when the patient walks. The rest of the limb is stabilized by means of a skeleton splint. It is particularly important in "dangle-foot" to bring the grafts across the mid-tarsal joint.

The Operation.

The following points are worth noting.

The Position of the Patient for Operation.—The prone position is best; this gives access to the backs of both malleoli, and allows the graft to be cut from the opposite tibia after flexing the knee (Fig. 3).

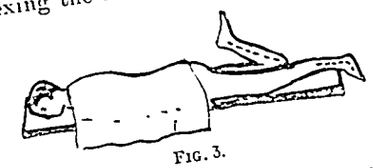

FIG. 3.

Skin Incision.—Time may be saved by making the three skin incisions—one extending to the foot from behind each malleolus, and one over the opposite tibia—in succession at the beginning of the operation. The scalpel is then discarded, and a second scalpel is used for the deep dissections. Side-curtains are fixed to the neighbouring wounds behind the ankle by means of Michel clips, to avoid a double encumbrance of towel forceps.

The Graft Bed.—Medially the tibialis posterior, and laterally the peronei, are displaced from their grooves, which are deepened by a gouge to form beds for the grafts; each groove must cross the mid-tarsal joint. The grafts are held in position by stitching the tendons over them: four stitches suffice for each graft. I do not permit either my own skin or the patient's to come in contact with the outer surface of my gloves. By this precaution I avoid the elaborate game of skill in which wound, graft, and sutures are treated as untouchable, and time is saved.

The Grafts.—I cut the osteo-periosteal strip, which is outlined by a scalpel, with a chisel of the same width as

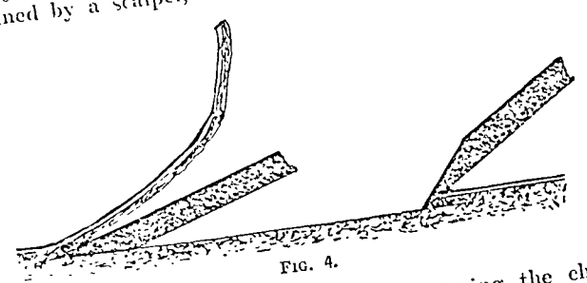

FIG. 4.

the subcutaneous face of the tibia—entering the chisel, bevel up, to the required depth, and then using it, bevel down, to shave off the strip (see Fig. 4). Then, holding the strip with tissue forceps by the four corners, I divide it longitudinally with straight scissors into two equal grafts. It does not seem to matter whether the graft has the pliability of wet paper or the spring of a hazel twig; the result is the same—a hinge, just distal to the malleolus, is ultimately formed in either case. The patient whose radiograph is shown in Fig. 2*a*, where the hinge is clearly seen, was grafted with tough, springy grafts, while in the girl's foot (Fig. 1) the grafts were flaccid.

Skin Closure.—Time is again saved, and contamination from skin is avoided by postponing the closure of all three wounds till the end of the operation. Michel clips are used instead of sutures, since the clips provide no path for infection. Rutherford Morison's invaluable thick layer of sterile boric powder is applied as a dressing.

After-Treatment.

The foot is bandaged for a week at right angles to the leg in an ordinary soft bandage; this permits the small degree of movement that produces the hinge in each graft. The Michel clips are then removed and the bandage reapplied. If there is any tendency to foot-drop or lateral deviation, or if the patient is unlikely to co-operate by remaining in bed, the limb is fastened to a long back splint, with the foot at right angles to the leg. A month after operation a plaster casing that extends above the knee replaces the bandage or the splint, and holds the foot in the same position. The patient is made to stand beside his bed on the plaster casing for increasing periods of time. The casing is removed two months after the date of operation, and the patient is encouraged to walk.

The Advantages of Hinge-Grafting.

1. The stability given by these bony hinge grafts improves with use; they do not stretch like tendons that are fixed or transplanted.

2. The after-treatment is simple: final and satisfactory function is obtained within three months—a time which compares favourably with the long period of care and re-education required after transplanting tendons.

3. If relevant muscles can still contract, the hinges allow movements of dorsiflexion and plantar flexion.

4. Hinge-grafting does not—like astragalectomy—disfigure the ankle.

5. It gives excellent results in "dangle-foot."

6. For talipes calcaneo-valgus it is the method of choice —not, I submit, another poor best among a disheartening array of forlorn hopes, but a thoroughly satisfactory treatment of the deformity.

FOUR CASES OF FRACTURED PELVIS.

BY

N. H. LINDSAY, M.B., B.Ch., B.A.O.,

HOUSE-SURGEON, ROYAL UNITED HOSPITAL, BATH.

(*With Special Plate.*)

THE interesting features about the following cases are the manner in which the lesions were produced, illustrating the different types of fracture caused by varying types of violence, and the fact that all four patients were admitted to hospital within a fortnight of each other.

CASE I.

T. D., a railway guard, aged 48, was admitted to hospital on January 17th, 1930, with a fracture through the symphysis pubis with rupture of the bladder. It was an incomplete fracture produced by compression violence. The patient fell from a station platform, and was caught between the platform and the running board of a moving train.

The following symptoms were exhibited. Extreme pain on compressing the iliac crests; inability to move the lower limbs without causing severe pain, but no evidence of nerve lesion; urgent desire for micturition; passage of a catheter withdrew a few drops of blood-stained urine.

The same day, after *x*-ray examination, the bladder was explored and the pubic symphysis exposed. A linear tear, a quarter to half an inch in length, at the junction of the anterior surface of the neck of the bladder and urethra was found and closed. The left superior ramis of the pubis was displaced downwards and backwards, being separated from the right superior ramus by about two inches. The displacement was corrected by manipulation and the fragments wired in position. A catheter was passed and tied in. Micturition was normal within forty-eight hours.

Further treatment consisted in the application of a stout pelvi binder and nursing on fracture boards.

CASE II.

R. M., a painter, aged 38, was admitted on January 22th, 1930, with a fracture through the floor of the acetabulum and right pubic bone. It was an incomplete fracture produced by compression violence. The patient fell from a ladder on to his right hip. When admitted he was suffering from shock and severe pain in the right hip and groin.

Examination showed that active movement of the right leg was possible but extremely painful. There was no tenderness on pressing the iliac crests together. The right leg was in a position of marked external rotation, full extension, and slight adduction. There was marked flattening over the right great trochanter and relaxation of the ilio-tibial tract, but no palpable abnormality. Shortening to the extent of one inch was present. There was no sign of injury to pelvic organs or nerves.

CASE III.

T. C., a window-cleaner, aged 60, was admitted on January 24th, 1930, with a fracture of the left ischial tuberosity. It was an incomplete pelvic fracture due to direct violence, and was produced by a fall on to the buttocks from an 18-foot ladder.

The lower limbs appeared normal in position and movements, but the latter caused pain in the region of the left sacro-iliac synchondrosis. Marked tenderness was present on pressing over the left sacro-iliac joint, and also per rectum in the region of the left ischial tuberosity. There was no sign of injury to the pelvic viscera, vessels, or nerves.

CASE IV.

B. W., collier, aged 42, was admitted on February 4th, 1930, with a fracture through the superior and inferior rami of the pubis on the right side and through the ilium on the same side, lateral to the sacro-iliac articulation; it was a complete fracture of the pelvic ring.

This patient was caught by his clothes in a revolving shaft, lifted in the air, and then violently dashed to the ground. On examination the right leg was held in a position of slight flexion and external rotation, with some flattening over the greater trochanter on that side. There was severe pain about the pelvis on moving the lower limbs, but no loss of function in the hip-joints. Compression of the iliac crests also caused severe pain, and slight crepitus could be elicited. Shortening of the right leg up to one inch was present.

Treatment of the foregoing cases consisted in proper immobilization of the injured areas by the use of sand-bags, where necessary, and tight binders. In Cases iii and iv extension was applied—in the former to both legs, in the latter to the right leg, counter-extension being maintained by raising the foot of the bed.

I am indebted to Mr. Fuller, Mr. Mumford, and Mr. Terry for permission to publish these cases.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CHLORETONE POISONING.

A RECENT paper by Professor J. J. van Loghem of Amsterdam[1] recalls to my memory the following case of chloretone poisoning which I met in my practice.

One morning about two years ago I was called to attend a Dutch lady who had crossed the Channel the night before and had taken Mothersill's remedy against sea-sickness. Her only complaint was that she had to lie in bed, for when she got up she had a feeling of having lost her balance and was unable to walk straight; when she tried she had a sensation as though she was walking on glass. She had no sickness or any other gastric symptoms. On clinical examination I found dilated pupils, all the well-marked signs of cerebellar disturbance, and the gait typical of a vestibular affection. Owing to her nervous condition she had a rapid pulse, but otherwise there was no evidence that any system except the central nervous system was affected.

After she had rested in bed for about twenty-four hours she was completely restored to her normal health. The only treatment I gave her was to administer a sedative and an aperient.

There was no doubt in my mind that the patient's symptoms had been brought about by an overdose of chloretone, which is the principal ingredient in Mothersill's remedy. I believe that 4 grains of chloretone are present in each powder. The dilatation of the pupils may, I think, have been due to the action of the scopolamine, which, according to Dannenberg,[2] is present in Mothersill's remedy. Chloretone poisoning is rare. Dr. W. Essex Wynter[3] and Dr. Donald Core[4] described cases in 1913. Two patients treated by the former showed signs of incoordination, vertigo, dullness of sensation, a sense of effort in movement, and mental confusion. The latter treated three patients in whom mental symptoms—incoherence of thought and speech passing to dullness and almost imbecility—supervened.

AUTO-BLOOD-TRANSFUSION.

IN his interesting article in the *Journal* of November 30th, 1929 (p. 1006), on auto-blood-transfusion in two cases of ruptured tubal pregnancy, Mr. H. B. Butler mentions Burch's four personal cases of auto-transfusion, one of which was after splenectomy, when much blood had been lost. The following case came under my observation while house-surgeon in the Glasgow Royal Infirmary in 1925.

A young man, aged about 26, who had been a patient on the medical side suffering from splenomegaly with anaemia, was brought to Mr. Kay's wards for splenectomy. The operation, performed under splanchnic anaesthesia and chloroform, was one of much difficulty owing to adhesions, as well as to the great size of the spleen.

I was instructed to stand by, scrubbed up as for assisting, and when the spleen was removed it was handed to me to invert over a beaker containing some sodium citrate solution. The shrinkage of the spleen as the blood ran out—about 1½ pints—was very marked. By the time it had ceased to run a senior assistant had the preparations ready for transfusing it back to the patient, while the surgeon finished closing the abdomen. The patient made an excellent recovery.

I am indebted to Mr. James Taylor, F.R.C.S.Ed., honorary surgeon, Glasgow Royal Infirmary, who performed the operation, for permission to record this case.

TENA GRAY, M.B., Ch.B.,
Hall Tutor in Surgery and Extra-Surgeon to the Out-Patient Department, Glasgow Royal Infirmary.

HYPERPYREXIA IN MEASLES.

THE following case of hyperpyrexia in the course of an attack of measles seems to me to be of more than usual interest.

On the morning of March 23rd I was called to see a child, 2 years old, suffering from measles. The rash was developing, and I noticed nothing unusual about the attack. The following morning, however, the father asked me to come at once as he thought the child was in a fit. I accompanied him to the house, and found the child in an apparently dying condition. Her skin had a pale slate colour; she had no convulsions and no rash. Every now and then she emitted a long-drawn sigh. When I took her temperature the mercury went up to 110° F.; it might have gone higher, but that is the limit registered by my thermometer. I at once put the child in a tepid bath and rapidly cooled the water down, letting it get quite cold. The temperature soon came down to 101° F., and I then put the child back in her cot and covered her with a light blanket. The temperature remained under 102° F., and she made an uninterrupted recovery. On the day following the attack of hyperpyrexia the rash appeared again and a week after the date when I was first called in the temperature was normal and the child seemed well. There were no other complications throughout the illness.

Reports of Societies.

TREATMENT OF GENITAL PROLAPSE.

AT a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on March 21st, with the president, Mr. ARTHUR GILES, in the chair, Professor FLETCHER SHAW read a paper on the treatment of genital prolapse.

Professor Shaw remarked that there was now general agreement that the uterus was held in position by the pelvic floor, and that prolapse of this organ, or of the vaginal walls, could only occur if the four tissues were damaged or weakened. The rational treatment for prolapse, therefore, was to repair and strengthen them by colporrhaphy. Professor Shaw gave a short history of the operation, recalling the fact that Donald commenced to treat prolapse of the uterus in this way in 1883, since when the operation had been almost the sole method of treatment of this condition in the Manchester school. As the result of investigating a series of cases treated from

three to seven years ago, he had received 293 replies to a questionary, which showed that there had been no recurrence in 282, or 96.2 per cent. The speaker pointed out that many patients who had been made comfortable with a pessary when young, ceased to be so after the menopause, when muscular atrophy weakened the supporting structures. Colporrhaphy was frequently performed in women over the age of 60 to 70 with excellent results. If the pelvic floor, after this operation, underwent the strain of labour, there was the possibility of recurrence, but most patients did not show any signs of it if time was given for the tissues to dilate. For many years the Manchester school had treated genital prolapse in young and old, parous and nulliparous, by colporrhaphy alone, with complete satisfaction. Professor Shaw described the operation by means of diagrams and a cinematograph film, and commended it as the rational treatment.

Mr. ARTHUR E. GILES, in a paper on the effect of hysteropexy upon subsequent pregnancy, and of pregnancy upon a previous hysteropexy, described his method of performing this operation. Three sutures of stout silk were passed through the anterior surface of the uterus as low down as possible, and through the peritoneum, muscle, and fascia. This left the body of the uterus free to extend in pregnancy, and no complication resulted. Of 1,424 hysteropexies, 765 were performed in married women, aged 40 or under; of those patients who had been traced, 107 had become pregnant, there being in all 139 pregnancies which had terminated in 110 deliveries at full time, and 24 miscarriages; in five instances the results had not been recorded. On an analysis of the miscarriages it was concluded that in no case was the operation responsible. The results of the labours were: natural labours, 50 cases; forceps delivery, 10 cases; induction for contracted pelvis, 2 cases; Caesarean section, 2 cases; and in two instances the results were not known. As regards the effects of pregnancy on a previous hysteropexy, out of 67 cases after a full-time confinement, 2 showed a return of the displacement. In 189 cases where pregnancy had not occurred the uterus had remained in good position in 179, and there had been recurrence in 10.

Mr. T. G. STEVENS agreed with Professor Fletcher Shaw as regards the treatment of prolapse, there being, he added, no need to open the abdomen in order to cure most cases of this condition. In about 2 per cent. of cases he had found it necessary to perform hysteropexy, or Gilliam's operation, on account of persistent retroflexion. This addition was, however, strictly to cure the retroflexion, which he believed was associated with backache of a severe character in some cases. He deprecated the teaching of those who often performed hysteropexy in addition to colporrhaphy as being likely to lead to a misuse of the former operation in inexperienced hands.

Mr. L. C. RIVETT rejected the suggestion that it was held at the Chelsea Hospital that hysteropexy alone would cure prolapse. The combination of a plastic vaginal operation with hysteropexy fulfilled what he considered the chief desideratum—namely, to make the patient comfortable. Sir EWEN MACLEAN described a case in which, after hysteropexy followed by pregnancy, the fundus was found to be anchored low by a thick band, the foetus being accommodated in a sacculation of the posterior wall. Dr. JAMES YOUNG thought hysteropexy was anatomically unsound, because it could not support the prolapsed bladder and vagina, nor prevent downward descent of the cervix. Plastic repair operations, if satisfactorily performed, rendered hysteropexy unnecessary, and eliminated the risk of abdominal section being required. He doubted the existence of such a low mortality as that in the experience of Mr. Giles and Professor Fletcher Shaw. Mr. CLIFFORD WHITE advocated plastic vaginal operations, but reported two deaths from pulmonary embolism. In his opinion hysteropexy was bound to prevent the proper expansion of the bladder. He emphasized the great discomfort of an abdominal as well as a perineal incision being made on the same occasion.

The president, Mr. ARTHUR GILES, replying, agreed with Professor Fletcher Shaw as to the badness of hysterectomy as the treatment of prolapse, but deprecated amputation of the cervix in every case, maintaining that hysteropexy rendered this generally unnecessary. When hysteropexy was performed for prolapse, it was combined with plastic vaginal operations also.

Hydatidiform Mole with Pulmonary Infarctions.

A communication was read from Dr. J. Eastcourt Hughes and Professor Cleland of Adelaide, South Australia, relating to a married woman, with two children, who was admitted to the Adelaide Hospital after two weeks' vaginal haemorrhage, following a period of amenorrhoea. Progressive weakness, shivering, marked shortness of breath, and an abdominal lump which rapidly increased in size, had been noticed four days before admission. The temperature was 98°, the pulse rate 104, and there was some cyanosis. The abdominal tumour nearly reached the xiphisternum, but showed no characteristic of pregnancy other than a uterine souffle. A rapid increase in cyanosis ensued, with drowsiness, culminating in death. At the necropsy the uterus was found to contain a hydatidiform mole; the lungs showed a considerable area of collapse, and the alveoli were filled with red blood cells, as in multiple infarctions of the lungs. Large masses of syncytium were found in the alveolar capillaries in these areas, and the spleen contained a small syncytial mass. Death was due to collapse of areas of the lungs with infarction from extensive flooding of the pulmonary circulation with masses of foetal syncytium.

PSYCHIATRY IN AMERICA.

AT a meeting of the Section of Psychiatry of the Royal Society of Medicine, on April 8th, with the President, Sir ROBERT ARMSTRONG-JONES, in the chair, two members who have recently visited the United States and Canada, Dr. EDWARD MAPOTHER and Dr. A. A. W. PETRIE, gave their impressions of American psychiatry.

Dr. Mapother said that during last August and September he had visited ten principal university cities in the United States, and also Toronto and Montreal. American psychiatry was not a single entity, any more than European psychiatry. There was no less independence between American States in his respect than between European countries. There was no federal unity in this matter. No general law existed, nor anything official comparable with the Board of Control as a nation-wide authority. The nearest approach to any unifying organizations were the national committees of mental hygiene of America and Canada. Four outstanding factors in America as he saw them were: (1) the enormously rapid growth of population, with consequent institutional shortage; (2) the extent to which official provisions at public expense were supplemented by bequests and donations, above all from such sources as the Rockefeller Foundation and the Commonwealth Fund; (3) the degree in which the American psychiatrist was master in his own house, a strange thing to a visitor from this "lawyer-ridden land"; (4) the far wider diffusion and higher level of psychiatric education of all kinds in America. The resultant of these factors was a greater tendency in America to look upon mental disorder as a problem to be solved rather than as a burden to be borne. The replacement of the static mind of the lawyer by the experimental spirit was one of the great guarantors of the future in America. The psychiatrist in America was allowed to manage his own affairs. In the most advanced States, Massachusetts and New York, the commissioner at the head of the Department of Correction, which carried out functions like those of the Home Office in penal matters, was a psychiatrist. In Maryland the commissioner for mental diseases had authority to transfer any person from prison to mental hospital. In the first two States mentioned all psychiatric provision was in the hands of a State department; there was no duplication, as here, between the local authority and the Board of Control, and the commissioner for mental diseases had powers beyond those which the Board of Control exercised. He had access to the governor of the State, and through him to the legislature, without any Minister or department intervening. The commitment law varied in different States from the extreme of legalism to the fundamental medical conception. Advanced medical opinion in the States was moving in favour of the total abolition of the judicial

authority in commitment procedure, and in Maryland the judicial order had been completely dispensed with; the patient could be committed for detention—not merely temporary detention—on the certificate of two medical practitioners. Actions for illegal commitment were no commoner than elsewhere, and hardly ever successful. As for psychiatric education, in at least ten American universities comprehensive courses of psychiatry were given in each of the four years of medical training. Many American students, however, went to Vienna for education in psychiatry, though in neurology Queen Square, London, was looked upon as the best centre in Europe. Dr. Mapother's general impression as the resultant of the four factors he had named was that in psychiatry America was chiefly interested in development, and England in maintenance. American arrangements seemed unfinished, like everything that was growing, and occasionally crude. In mentioning a few individual hospitals, he instanced Bloomingdale, near New York, as comparable in structure and maintenance with the registered hospitals in England. The Phipps Psychiatric Clinic, Baltimore, was comparable with Maudsley, but not State-supported, nor providing in any considerable measure for the poor. It was here, and at Boston Psychiatric Clinic and Cornell Clinic, New York, that he saw the best out-patient departments of his tour. He criticized some details in the interior arrangement of institutions, especially the "neo-lavatorial" style of decoration in the observation wards, excellent, no doubt, for washing-down purposes, but not easy to reconcile with a homelike atmosphere. As for staffing arrangements, the accepted proportion of doctors to patients was 1 in 150. Such a ratio would double the number of medical officers in the county mental hospitals of London. Salaries were about the same as in England; in view of the scale of American incomes Dr. Mapother thought this involved a lower status. Finally, speaking as one who had had glimpses of psychiatry in ten European countries, he felt that the psychiatric future was more secure in America than in Europe.

Dr. A. A. W. PETRIE said that he had started on his tour with some insular prejudices, and found that a number of them had to be distinctly modified. In America he found departures from British methods, some advantageous, others disadvantageous, still others merely ways of doing things differently. The chronic patients in the large State general hospitals were no better dealt with than in England. Overcrowding existed in many places, especially in the chronic sections in Chicago and Manhattan, New York. The new admission hospital sections impressed him favourably. The "diagnostic corridor" in the new admission centre in New York was fitted up for all the various consultants, and enabled them to see their patients under good conditions. The nursing staff was divided sharply into nurses and attendants, according to preliminary education, but the methods of training attendants were exceedingly poor. Hydrotherapy was very good, occupational therapy well developed, and gymnasium classes more usual than in this country. Out-patient departments were generally in operation in the American mental hospitals, an advantage not only from the point of view of the patient, but from that of the staff, who were thus kept in touch with the early manifestations of the disease. At Bloomingdale, New York, 70 per cent of the cases were received as voluntary; elsewhere the percentage was much smaller. Opinions varied as to what was the best size for a hospital, the accommodation ranging from 2,000 in Massachusetts to 10,000. The psychiatric clinic had been greatly developed, and served as a reception unit. The Phipps Clinic was attached to Johns Hopkins, a similar clinic in Philadelphia to the University of Pennsylvania, and, in New York, to the New York State Department. The length of residence in Phipps was rather less than two months. The cost of a case in a clinic was roughly about £10 a week.

Sir ROBERT ARMSTRONG-JONES, from the chair, said that it was not easy to speak of American psychiatry without paying a warm tribute of admiration and respect to the work of Dr. Benjamin Rush, who was educated in Edinburgh and London, who knew St. Luke's and Bethlem, and who began his work as a member of the Society of Friends in the Pennsylvania State Hospital for the insane. He and Dr. Thomas S. Kirkbride were pioneers in the humane and sympathetic treatment of the insane in America. They were contemporaries of Tuke in York, Pinel in France, and Connolly at Hanwell. They began their work about 1751, and continued it until 1813. The name of Dorothea L. Dix, the "Florence Nightingale of psychiatry," should also be recalled. The president added that he believed that the United States had no general lunacy code, and therefore no uniformity in dealing with the insane, for each State could build its own asylums and hospitals and levy its own taxes. The supervision of the asylums was also a matter for each separate State, and was carried out by the governor or by the State legislature. Certification was different in America from what it was in England. In six States a jury decided the question of insanity; in six States there was a permanent commission for each county, which decided whether a case was to be custodial or temporary and for early treatment. In over thirty States either one or two doctors swore before a justice or magistrate as to insanity, and the judge ordered detention on the medical certificate. The receiving places in America were: (1) the Government asylum—he believed there was only one, near Washington, for soldiers and sailors; (2) the State asylums or hospitals, county or municipal; (3) incorporated hospitals, such as those provided by religious bodies; (4) private asylums, the result of private enterprise; and (5) out-patient departments of general hospitals, or perhaps beds in such institutions.

Dr. KUHN, an American medical practitioner, while protesting that American psychiatry was not all of one pattern, and must not be judged as a single entity, remarked that in certain respects America could learn from Great Britain, for he knew nothing in America comparable with the work of the Tavistock Square Clinic.

HIGH BLOOD PRESSURE.

AT a meeting of the Harveian Society of London, on April 10th, an address was delivered by Sir THOMAS HORDER on the subject of high blood pressure.

Sir Thomas Horder said that the largest group of these cases which presented themselves to the physician was that in which the diagnosis was definitely arterio-sclerosis. These patients came at various stages of their disease, and their symptoms were protean, including shortness of breath, heart consciousness, true or "false" angina, sometimes chronic uraemia or renal insufficiency, haemorrhages, and thrombosis. The next largest group consisted of those in whom arterial tension was easily demonstrated and symptoms had developed, the two being associated in the mind of the patient and of his doctor, and yet critical examination revealed no certain organic changes in the blood vessels, heart, or kidneys. There was a third smaller group in which the renal element was so dominant that the patients were spoken of as suffering from nephritis. Some of the highest blood pressures occurred in this group, especially in women. These people nearly always died from uraemia. Disregarding the first and third of these groups, Sir Thomas Horder said that the second group of what he called hyperpietics could be subdivided. First of all there was a group of plethoric patients, chiefly males, often of sedentary habit, with obesity and here it was a little tempting to suggest that in some of these hypertensions, even if due to the presence of toxic principles in the blood stream, was at first compensatory in the direction of increasing metabolism and elimination. A second small group consisted of patients in whom a genous poisonous agents from outside—were dominant, of these poisons alcohol was by far the commonest, and this group chiefly consisted of persons who were drinking too much and had high pressures in consequence. A third group consisted of menopausal hyperpietic women. One of the most established experiences in medicine was to watch a woman entering the phase of hyperpiesis in the forties, and afterwards gradually—sometimes abruptly—returning to the range of normal pressures. It was the view that the discomfort of the menopausal state was due to hypertension. Some believed that the flushing and sweating, the vasomotor disturbance, and nervous irritability were actual effects of the hypertension, but this was difficult to establish. At one time he thought a systolic pressure of 175

was the limit above which a woman at the climacteric should be considered the subject of organic arterial disease. He had ceased now to say what degree the systolic pressure in a woman who had marked menopausal symptoms must reach for disease of the cardio-vascular system to be diagnosed. He believed there were a few men who, later in life than women, went through such a state, and with it a period of hypertension; but a relative and temporary hyperpiesis occurred sometimes at puberty, chiefly in boys, concerning whose hearts there was often some discussion, who had tiresome sexual difficulties, and whose brachial arteries, a certain school of cardiologists declared, were thickened, though he had never been able to ascertain how that was estimated. Some of these boys had strained their hearts, and possibly the hypertension might be a compensatory feature. Yet another subgroup of hyperpieties consisted of the nervous class. What was often called high blood pressure might in their case be termed high nerve pressure, because there was a close dependence between these two things. In many of these patients the mere knowledge that their pressure was high sufficed to keep it high. These were knowledgeable people, and talked in terms of blood pressure rather than of primary sensation. They were victims of their nervous system rather than of their circulation, a prey to emotional strains which might be ended by the time they sought advice, but the circulation took a long time to readjust itself. Against a postulated final group he put certain questions. Was there such a thing as essential hyperpiesis? Were there patients in whom high blood pressure was present for the whole or a considerable part of their lives, independent of the menopause or of structural changes which could be demonstrated, or of any adequate toxic factor? Was hypertension the expression of an endocrine disturbance, and was it the pituitary gland which was in a state of dysfunction? He supposed the favoured doctrine with regard to hyperpiesis in general was that somewhere in the body there was a "dug-out" of focal sepsis, or possibly diffused sepsis—for he had often wondered whether too much attention was concentrated on focal sepsis, dental or tonsillar, when perhaps the whole of the upper respiratory tract or some length of intestine might be responsible. An earlier generation of medical men, who had no sphygmomanometers, said of these persons that they had gout, and possibly that diagnosis was as wise as the eternal search for focal sepsis. There were waves of hypertension which came to complicate the course of these cases. What was the meaning of these exacerbations? Patients known to be high blood pressure subjects might go for a long time not complaining of any symptom, and then the hour arrived when the condition seemed to speed up.

As to prognosis, hypertension was always, of course, of serious significance until organic disease had been excluded, and even then it was a condition to be treated with respect. Nothing, except cancer, seemed to alarm the lay mind so much as a "stroke," and the lay mind had a right instinct in this as in other respects. With some of the groups he had mentioned, such as the epochal cases and nervous cases, and cases where there was a definite cause like alcohol, a favourable view might be taken, but he disliked especially those cases in which careful investigation failed to reveal anything, just as he disliked cases of angina in which there were no physical signs. To discover hypertension at the earliest possible moment was, of course, of great service to the patient. It might not be possible to change the temperament, but the patient's outlook could be modified in such a way as to diminish stresses and strains, and occasionally a man might be made a philosopher before some crippling catastrophe thrust philosophy upon him. It was well to practise reassurance, because, if the patient accepted it, it was a therapeutic measure. In other conditions, such as cancer, reassurance did no more than bring mental comfort, but in high blood pressure it had a definite effect on the condition itself. It was well to explain to the patient that he was not suffering from a disease, but that his pressure was an expression of something wrong for the time being, and might even be not a bad thing, as an effort of nature to adjust the circulation. It was well not to alarm the patient by taking readings too often. He was never quite satisfied that these patients should be vegetarians; omitting stimulants and extractives, he allowed them butcher's meat two or three times a week. He did not believe that copious amounts of fluid were good, for they cast a strain on the kidneys; blue pill and salines might be useful. Warm baths—neither hot nor cold—were to be advised. The use of drugs to lower tension was undoubtedly disappointing; iodine and iodides perhaps headed the list of useful drugs, with nitrites for occasional use, and, paradoxical as it might seem, he used digitalis in a number of cases with advantage, for some of these patients needed cardiac tonics. Before writing a programme of treatment he bore in mind five factors: (1) the heart, to assess what it was doing; (2) the kidneys, and the question of secretory function; (3) the arteries, whether organically diseased; (4) the nervous system, especially the emotional and mental state; (5) the tissues, whether toxic in the microbic or metabolic sense, or affected by some exogenous chemical substance like alcohol.

Dr. GEOFFREY EVANS asked whether there was a difference between functional and organic hypertension except in so far as it was presumed that in the former there was merely a change in function and in the latter a change in function with a change in structure. There was in this complaint a pathogenic agent which simultaneously caused a change in function and in structure, one or other change predominating in the particular case. Dr. J. F. HALLS DALLY said that high blood pressure was a symptom of a good many causes; until the underlying factors were known it was difficult to formulate scientific treatment. It was necessary to adapt the diet to the minimum metabolic needs of the individual, cutting down the bulk of each meal, limiting the meat with the idea of avoiding fermentation and putrefaction if there was any tendency to intestinal stasis. He combated the adage that a man was as old as his arteries; many people did extremely well although their arteries were like gas-piping. The crux of the problem rested with the kidney, and he drew a sharp distinction between the patients with no evidence of renal dysfunction and others in whom there was such evidence; the prognosis was much worse with the latter.

Dr. A. H. DOUTHWAITE referred to the need for bringing down the pressure in those cases which had periodical rises, resulting in symptoms lasting for weeks, especially in the sallow thin type, often overlooked and labelled neurotic. Two lines of treatment held out hope—periodical venesection and the injection of acetylcholin; in hyperpiesis without marked arterial change this drug brought about a semi-permanent fall in the blood pressure. Dr. ADOLPHE ABRAHAMS said that the boys at puberty in whom, Sir Thomas Horder had suggested, high blood pressure was compensatory to heart strain, might perhaps be unmasked cases of renal disease. The whole subject would be much easier if high blood pressure was always correlated with symptoms, but some persons with very high pressures complained of nothing. Hypertension must not be always regarded as connoting arterio-sclerosis; there must be many cases of arterio-sclerosis with low pressure. Dr. GILBERT ORMIE referred to his experience in a milling town in the North of England where he found definitely in men between the ages of 40 and 46 something which appeared to be a menopause, with a very distinct rise in blood pressure. It continued for about two years, and to a large extent was influenced by the administration of bromides and sodium bicarbonate; he always advised a morning dose of saline. A frequent symptom was a chronic headache, exacerbated by the noise of the mills. In patients who did not die, the blood regained more or less normal tension. Dr. R. COVE-SMITH spoke of the difficulty of fixing a definite standard; perhaps each individual had his own normal. He thought digitalis was indicated in some cases of arterio-sclerosis, particularly if a load was falling on the heart, for the myocardium was the most important factor in maintaining circulation.

Sir THOMAS HORDER replied that he made no rigid distinction between "functional" and "organic"; the terms were misused and lacked exact significance. He still thought it was a good dictum that a man was as old as his arteries, but he applied it to that steady progressive thickening of the vessels which led to apoplexy; otherwise it might be said that a man was only as old as his capacity for repair.

Reviews.

SURGERY OF THE TONSILS.

As an objective of surgical attack, the tonsil has in the last ten or fifteen years become of vastly increased importance, due largely to the recognition of the part it plays in the production of focal sepsis. There are also the local conditions which arise and the relation of the tonsils to tuberculosis of the cervical glands, but all this would scarcely justify the lordly volume on *Tonsil Surgery*,[1] by Dr. ROBERT FOWLER, unless he had something fresh to say. His justification is that he has made a very complete study of the anatomical relations of the tonsil, a matter which has been strangely neglected considering the frequency with which tonsillectomy is now performed.

In a series of splendid anatomical plates Dr. Fowler shows that the tonsil is not in direct relation to the superior constrictor of the pharynx, but is separated from it by the palato-pharyngeus. This muscle spreads out behind and sends a slip, which he calls the tonsillo-pharyngeus, somewhat analogous to the salpingo-pharyngeus, to be directly attached to the tonsil. This accounts for the frequency with which muscle fibres are found on the capsule of excised tonsils. The nature and production of the tonsillar capsule, whose very existence has been denied, is carefully described, but it is sufficient to say that everything relating to the anatomy and embryology of the tonsil is to be found in this book. This is accomplished and illustrated in so fascinating a manner that dismay at the prospect of another work on the tonsil is soon changed to gratification. There is a comprehensive review of the various methods, whether by guillotine or dissection, of removing the tonsil. The author is not an outspoken partisan of any particular method, but the book does form an eloquent plea for more precise operating with avoidance of unnecessary haemorrhage and damage to the pharyngeal muscles and mucous membrane. In connexion with this he quotes Dr. George Fetterolf as follows: "The result is that many incomplete operations are performed, and more tonsils are added to that long and shameful list of those which have 'grown again.'" These are words which must carry great weight when the frequency of secondary and even tertiary operations is borne in mind. There is no need to labour this point, except to emphasize the extreme value of this magnificent volume to all who practise these operations.

To those who are satisfied with their technique, with its anatomical basis, and with their results, this book has no message. It will prove invaluable to those who wish to clarify their anatomical knowledge, to improve the details of operative technique, and to obtain uniform results.

ARTIFICIAL PNEUMOTHORAX.

THE Practice of Pneumothorax,[2] by Drs. F. DUMAREST and P. BRETTE has appeared in a third edition, with an addition to its subject-matter under the title of "La collapsothérapie chirurgicale." The book is now double the size of the first edition, published in 1918, and this steady growth, and reappearance, are the best witnesses of its merit. It will be read with interest and advantage by even experienced collapsotherapists, if we may be allowed to coin an even more formidable word than the authors have in their title, while for those who are at the beginning of their career in tuberculosis work it will be found to be an excellent companion volume to our English work on the subject by the late Clive Riviere.

The first 200 pages deal with the ordinary artificial pneumothorax, its induction, maintenance, and complications. Then follows a short account of oleothorax and pleural lavage. The next section, on thoracoscopy and the cauterization of pleural adhesions, is also short. The next twenty pages deal with after-results, and contain a most excellent *vue d'ensemble* in which Burnand's wise words, "le pneumothorax ne dispense pas de la cure," serve as a text. Following this are two chapters on the mode of action of collapse and the indications and contra-indications for its use. Ten pages only, alas! are allowed for bilateral pneumothorax, and the last forty deal with surgical methods and thoracoplasty. The book finishes with a series of illustrative *x* rays and a full bibliography.

There is a humility about the whole work which makes it far more convincing than if the subject was treated in a dogmatic manner, which so often obscures real value by irritating the argumentative reader. Most reviewers of technical works, however greatly they may admire the book under discussion, are tempted to tell the authors how much better their work would have been if it were laid out and balanced differently. In this case the temptation must be resisted, since the ordering of the different sections has obviously been done with great care and thought. One mild criticism may, however, be made—namely, that the authors have been rather parochial in their description of apparatus. One would like to see, for instance, a mention of Dr. Parry Morgan's excellent instrument with its double manometer, or among the portable ones Heaf's, and of Clive Riviere's inducing cannula and trocar. But this is a trivial matter; it is an excellent book.

ANATOMICAL ILLUSTRATION.

THE seventh edition of Dr. SOBOTTA'S *Atlas der deskriptiven Anatomie des Menschen*,[3] Part 1, reaches a very high standard in the technique of anatomical illustration. It would hardly be possible, indeed, to surpass in perfection the 349 figures which comprise the essential part of this volume. Anatomical illustration is a specialized art, which demands for its successful execution a compromise between realistic representation and diagrammatic clarity. The more vague and ill defined the tissues and organs, the more must realism be sacrificed to the lucidity of conventionalization. Thus, as this atlas shows, osteological figures may be very faithful reproductions of the actual appearance of bones. The illustrations of muscles, especially those whose outlines are not sharp and clear in the real (such as the facial muscles) are much less true to life, while the ligaments are necessarily represented in a still more schematic manner. It may be said that no anatomical illustration can completely escape the artificiality of a schematic diagram, but it seems that, except in one single instance, the artist of Sobotta's *Atlas* has carried realism in his figures to the highest point without in any way detracting from their clearness. The exception noted is to be seen in Plates 1, 2, and 3, where the subcutaneous bursae are pictured as clean-cut sacs such as they only appear under pathological conditions.

The new edition is enriched by the addition of *x*-ray illustrations of the skeleton taken from Grashey's *Atlas*, and the accompanying text showing the normal variation in the dates of the appearance of secondary centres of ossification is of great value. This atlas cannot but be of the greatest assistance to the student of anatomy, and it is equally certain that it will provide a means of rapid revision of anatomical structures and relations for the practising clinician.

PSYCHOLOGY.

IN a book the English translation of which is entitled *The Psychology of the Infant*[4] Dr. SIEGFRIED BERNFELD deals with the development of the child from what he terms "the trauma of birth" to "the trauma of weaning." It might be thought difficult to find enough relevant material to fill over 300 closely printed pages with a study of the psychology of the child during the short period from birth to weaning. This work, however, makes it evident that an intensive study of these early days of child life brings into

[1] *Tonsil Surgery*. By Robert H. Fowler, M.D. Philadelphia: F. A. Davis Company. 1930. (7½ × 11, pp. 283; 102 figures. 10 dols. net.)

[2] *La Pratique du Pneumothorax Thérapeutique et de la Collapsothérapie Chirurgicale*. Par F. Dumarest et P. Brette. Préface du Professeur F. Bezançon. Troisième édition de *La Pratique du Pneumothorax Thérapeutique*. Paris: Masson et Cie. 1929. (Med. 8vo, pp. xiii + 409; 54 figures, 30 plates. 50 fr.)

[3] *Atlas der deskriptiven Anatomie des Menschen*. Von Dr. med. J. Sobotta. I Abteilung. Siebente Auflage. München: J. F. Lehmann. 1930. (Post 4to, pp. viii–278; 342 figures. Bound, M.27.)

[4] *The Psychology of the Infant*. By Siegfried Bernfeld. Translated by Rosetta Hurwitz. Library of Educational Psychology. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1929. (Demy 8vo, pp. xi + 309. 15s. net.)

the foreground many problems of fundamental importance and profound interest which merit the fullest discussion. Dr. Bernfeld has adopted Freud's contributions to developmental psychology as the basis of his monograph, and he has made it his special aim to demonstrate their fruitfulness for the understanding of facts established from other sources, and for the development of the fundamental ideas of other schools. Especially interesting to the general psychologist will be the inferences the author draws from the objective behaviour of the child as to the characteristics of its phenomenal world. In common with the *Gestalt* school Dr. Bernfeld rejects the older conception of "original chaos," and believes that at an early age the perceptions of the child are of the adult kind, in the sense that it perceives structures and their relation to itself, modified by memories of its personal experiences. This is an interesting and able work—a definitely useful addition to psychological literature.

Pleasure and Instinct,[5] by Mr. A. H. B. ALLEN, is an eminently clear and readable monograph on the much discussed problem of the nature of pleasure and "unpleasure." The subject-matter is divided into six parts, dealing in turn with the principal theories of pleasure-pain, sensory pleasure and unpleasure, pleasure and unpleasure in relation to the main instincts, the psychological nature of pleasure and unpleasure as compared with sensation, pleasure and desire, and the psychology of values. Since this work amplifies some of the most important aspects of general psychology, the student will find it useful to read in conjunction with his textbook.

An Introduction to Individual Psychology,[6] by Miss ALICE RAVEN, is a contribution to popular psychology based in the main on the teaching of McDougall. On the practical side the writer would appear to have been influenced by the "power" psychology of Adler, and throughout this work she aims to keep before the mind of the reader the idea of a positive and courageous attitude to life. Those who wish to acquire an elementary knowledge of the human mind from the standpoint of dynamic psychology will find this little book interesting and helpful.

CLINICAL PAEDIATRICS.

WE have received from the publishers three further volumes of *Clinical Pediatrics*,[7] a series of monographs appearing under the general editorship of Dr. R. S. HAYNES. Vol. 16, on *Diseases of the Skin in Infancy and Childhood*, is by Dr. HOWARD FOX, professor of dermatology and syphilology in New York University. It is intended as a practical guide for medical practitioners who have not made a special study of skin diseases; and emphasis is, accordingly, laid on clinical description, differential diagnosis, and treatment, rather than on etiology and pathology; the scheme of classification is frankly a compromise. Vol. 17, on *Prepubescent Syphilis*, is by Dr. PHILIP C. JEANS, professor of paediatrics in the Iowa University School of Medicine, and Dr. JEAN V. COOKE, associate professor of paediatrics in the Washington University School of Medicine. Here again the authors' object is to present their subject—syphilis in children—from the standpoint of the practitioner and student of medicine. The work is based upon personal experience during sixteen years, during which time more than 1,500 syphilitic children were studied and treated. Vol. 18, on *Heart Disease in Infancy and Childhood*, is by Dr. CHARLES H. SMITH, professor of clinical diseases of children, Columbia University, and his colleague Dr. LUCY P. SUTTON. As is only natural, a large part of the text is devoted to rheumatic fever and its effects on the heart of the growing child. A chapter on electro-cardiography is contributed by Dr. GERTRUDE H. B. NICOLSON. Each of these three volumes is well printed and copiously illustrated. We understand from the publishers that two more monographs may be expected to complete the series, and that the catalogue price of the set of twenty volumes will be £16, making the net cost of each volume 16s.

[7] *Clinical Pediatrics*. New York and London: D. Appleton and Co. 1930. Vol. 16: *Diseases of the Skin in Infancy and Childhood*. By Howard Fox, M.D. (6½ × 10, pp. xxix + 372; 110 figures.) Vol. 17: *Prepubescent Syphilis*. By Philip C. Jeans, M.D., and Jean V. Cooke, M.D. (6½ × 10, pp. xxi + 295; 96 figures.) Vol. 18: *Heart Disease in Infancy and Childhood*. By Charles Hendee Smith, B.S., M.D., and Lucy Porter Sutton, M.D. (6½ × 10, pp. xvi + 259; 97 figures.) 48s. the three volumes.

NOTES ON BOOKS.

THE revision of the sixth edition of BORRADAILE'S *Manual of Elementary Zoology*[8] consists in minor alterations of the text and of some of the figures. We have already directed attention to the comprehensiveness of this work, which has been found of special service to medical students.

The Interns Handbook[9] is an interesting pocket volume compiled by members of the Faculty of the College of Medicine of Syracuse University. Its purpose is to tell the newly qualified practitioner, who is entering on a house appointment, what to do and what to prescribe. The volume deals in a brief and competent manner with the usual subjects, such as treatment of poisoning, clinical examination, clinical pathology. It also includes matters that are less frequently described. For example, it tells the intern how to prepare a patient for x-ray examination or treatment, and there is a short but useful chapter on special diets. The most novel feature, however, is two lists—a physicians' drug list and a pharmacy list. These lists are remarkably short, their purpose being to clear the hospital pharmacies of many expensive "nostrums" and "specialties." The preface contains some interesting aphorisms concerning the use of drugs, of which the following are examples. "To anyone familiar with drug prescribing in hospitals it is not amazing that in the last decades drug nihilism has flourished despite a great increase of scientific knowledge of pharmacology and its therapeutic application." "Drug therapy will become rationally flexible only by prescribing fewer drugs, whose actions are fully known to the prescriber." The book strikes us as an interesting and useful attempt to rationalize clinical treatment. Its production is certainly evidence of a happy spirit of co-operation among the staffs of the College of Medicine and of the hospitals which collaborated in its production.

Winter Sport in Europe,[10] by Mr. BECKET WILLIAMS, is a collection of personal impressions of various centres in Austria, France, Switzerland, and Scandinavia, with notes of resorts in several other countries. These impressions are prefaced by brief accounts of the countries themselves. While the book has introductory value as a compact guide it is marred by superficial digression and by an execrable style. The section about Austria is not free from misspelling. Most of the photographs have been supplied by railway companies and travel bureaux.

PREPARATIONS AND APPLIANCES.

A MODIFIED CAPSULE FORCEPS.

DR. G. F. ALEXANDER (Scarborough) writes: Failure is apt to occur in the course of a capsulectomy owing to the teeth of the forceps refusing to bite into the capsule, this being specially the case in hypermaturity, from toughness of the capsule or fluidity of the cortex. While the teeth should be as sharp as possible, they materially tend to bite into the capsule the more vertically they are inclined to it.

A more vertical inclination of the teeth to the capsule than is possible with the usual pattern of forceps is obtained by setting them on short primary arms, which in turn are opened and closed by long secondary arms. The latter are given a ring grip, and provided with a screw stop to limit the range to which the teeth can separate to a distance not exceeding 4 mm. The heels of the short arms are not only separated to the extent of 1 mm., but are raised 1 mm. above the level of the teeth, so that they cannot possibly grasp the iris.

The forceps illustrated have been made to my design by Messrs. Down Bros., St. Thomas's Street, S.E.1.

POST-GRADUATE MEDICAL EDUCATION.

SCHEME FOR A HOSPITAL AND MEDICAL SCHOOL IN LONDON.

IN January, 1921, Dr. Addison, the first Minister of Health, appointed a Post-Graduate Medical Committee, under the chairmanship of the Earl of Athlone, "to investigate the needs of medical practitioners and other graduates for further education in medicine in London, and to submit proposals for a practicable scheme for meeting them." That committee presented its report within four months, and a full account of its findings and recommendations appeared in the *British Medical Journal* of June 25th, 1921 (p. 942). Its clear statement of the situation brought to light two outstanding defects in the provision made in London for post-graduate education. The first defect—lack of adequate provision for instruction in public health and cognate subjects, and for research in preventive medicine—was remedied in 1922 by the establishment of the London School of Hygiene and Tropical Medicine, which was made possible by a munificent gift from the Rockefeller Foundation. The second defect still remains. There is no hospital and medical school in London exclusively devoted to providing practical courses for doctors in this country, from the Empire overseas, and from other countries, who wish to refresh their knowledge or to get instruction in new developments of medicine, surgery, and obstetrics, or to participate directly in the clinical practice of the hospital.

This in brief was the position confronting the Post-Graduate Medical Education Committee, which was set up in July, 1925, "to draw up a practicable scheme of post-graduate medical education centred in London." Mr. Neville Chamberlain, who appointed this second committee, himself presided over it for four years, and Mr. Arthur Greenwood, his successor as Minister of Health, became in turn its chairman last summer. The other members were Sir George Blacker, Sir John Bland-Sutton (who resigned in November, 1926, and was succeeded by Lord Moynihan), Sir Robert Bolam, Dr. H. G. Dain, Lord Dawson of Penn, Mr. H. L. Eason, Sir Thomas Horder, Professor Hugh MacLean, Sir George Newman, Dr. John Parkinson, Mr. H. J. Paterson, Sir Arthur Robinson, Sir Humphry Rolleston, and Mr. A. E. Webb-Johnson. Of these, Sir George Newman was the only member who had served also on the Athlone Committee.

As announced in our last issue (p. 709) the report of the Post-Graduate Medical Education Committee was issued on April 9th, and simultaneously the Minister of Health informed the House of Commons that the Government had accepted its recommendations for the organization of a British Post-Graduate Hospital and Medical School. A report of Mr. Greenwood's speech appears in our Parliamentary Notes this week. In an explanatory memorandum issued officially to the press it has been stated that the Government "is satisfied, after careful consideration, that the scheme put forward by the committee is a practicable scheme, indeed, probably the only practicable scheme in sight. . . . They are much impressed with the importance of securing without avoidable delay the advantages of a proper system of post-graduate medical education in London, not only from the domestic, but also from the imperial and international point of view."

REPORT OF THE POST-GRADUATE MEDICAL EDUCATION COMMITTEE.

The committee's report,[1] a printed document of 38 pages signed by all the members, opens with a few words about the obvious need for the continued education of medical practitioners, and then briefly outlines the inadequate provision hitherto made in this country for supplying that need. Mention is made of the early effects, under the leadership of Sir Jonathan Hutchinson, at the long defunct Medical Graduates' College and Polyclinic, and a tribute is paid to the pioneer work done during the past eleven years by the Fellowship of Medicine and Post-Graduate Medical Association—work which "undoubtedly emphasized the need for a post-graduate hospital in London." A short section on the present urgency of the problem gives examples of recent practical discoveries and additions to knowledge, in order to show the importance of increasing such facilities as already exist for post-graduate medical education.

"Apart from these major and specific advances, it is of the utmost benefit both to practitioner and patient that practitioners in their daily work should have at their command an up-to-date knowledge of continuous technical progress which is being made in such matters as co-ordination of clinical and pathological methods, administration of anaesthetics, taking and examining specimens of blood, and numerous forms of minor surgery. Further, the trend and development of relations between medicine and the well-being of the people has brought about in this and other countries a series of general and local Acts of Parliament establishing social medical services for the purpose of promoting industrial welfare, coping with domestic problems of sanitation and personal hygiene, and reducing incapacity for work caused by sickness. A new need has thereby been created for the medical practitioner to appreciate what may be called social aspects of medicine, and to qualify himself to participate in the working of social medical services."

Need for a Hospital and School in the Metropolis.

After signifying general agreement with the recommendations arrived at as a result of the full and authoritative inquiry made by Lord Athlone's Committee, the report explains the outstanding need for a post-graduate hospital and medical school in London, from three points of view: (*a*) its imperial and international value, (*b*) its national value, and (*c*) its special value to the country doctor. In regard to (*a*) it says:

"A properly organized post-graduate hospital and medical school, such as the Earl of Athlone's Committee had in view, with a staff of visiting experts including acknowledged leaders in medicine and surgery, would attract, and should be of immense value to, students from the Empire and abroad who at present have no means of taking advantage of practical work accomplished in this country. The provision of effective post-graduate teaching in London is therefore not in any sense a narrowly national problem."

In regard to (*b*)—further scientific training of practitioners in this country after they have qualified—the committee agrees with its predecessor as to the undesirability and impracticability of attempting to teach undergraduates and post-graduate students in the same school.

"Yet the knowledge and experience possessed by the undergraduate at the moment when he qualifies needs to be supplemented, after his qualification, by post-graduate instruction. There are obvious and inevitable limitations to undergraduate teaching in medicine, not only because the curriculum cannot be further loaded, but also because it is impossible to give to the young student that degree and kind of participation in direct medical treatment of the patient which alone can complete the competence of the practitioner either in general practice or as a specialist. Further, a British Post-Graduate Hospital and Medical School established in London would have an important influence in bringing about a closer interrelation than exists to-day between the twelve hospitals in London having medical schools with great resources of experience in the science and art of medicine and the development of medical skill."

Under (*c*) it is pointed out that if further post-graduate teaching in London could be made easily accessible to the country doctor, great benefit should result to the doctor, and through him to his patients.

"It is still the case throughout the rural parts of Great Britain, and even more in other countries within and beyond the Empire where populations are sparser, distances greater, and communication more difficult, that the country doctor must usually do his work in some degree of isolation. The problem is how to keep him in touch with new developments in medicine and surgery. In this country he leaves his hospital on graduation with a training as prolonged and complete as it is possible to attempt with a large body of students. But once he has become absorbed in practice he has few opportunities, even though he is fortunate enough to join the staff of a local hospital, to keep his knowledge up to date. There is a great need of short and highly concentrated refresher courses for such men. In this country an experiment on a small scale has been and is being made by arranging such courses in certain centres for practitioners isolated in rural areas whose practices consist in part of work under the National Health Insurance Acts. These courses, few and restricted in scope and duration as they are, have been greatly appreciated by the practitioners who have taken part in them.

"It is an example and an example only, of the value of a British Post-Graduate Hospital and Medical School that recourse to its facilities might fairly be expected to maintain and increase the efficiency of medical service provided for over sixteen and a half million men and women in Great Britain under the National Health Insurance scheme, if year by year a certain proportion of

[1] Cmd. 3585. London: H.M. Stationery Office. 1930. 9d. net.

the seventeen thousand insurance practitioners, particularly those who are remote from any important hospital centre, could be given a chance of taking carefully planned refresher courses."

The committee then proceeds to examine the nature and conditions of "a practicable scheme" for the establishment of a post-graduate hospital and school centred in London. In dealing with the problem it arrived at the scheme which it recommends after considering and ultimately deciding that it could not support various alternate methods. The schemes considered but not recommended were (1) the building and maintenance of an entirely new institution; (2) the conversion of an existing voluntary hospital having a medical school; and (3) the conversion of an existing voluntary hospital not having a medical school. The grounds for rejection in each case are carefully stated. In regard to (3) the committee acknowledges the prolonged and laborious collaboration which the authorities of the West London Hospital undertook with it, and explains at length the reasons which eventually induced it not to recommend conversion of that institution into the British Post-Graduate Hospital and Medical School.

At the moment when the committee was endeavouring to find means of removing the difficulties in the way of an arrangement with the West London Hospital—the only practicable scheme which had up to then presented itself during more than three years of deliberation—another alternative emerged during the early months of 1929. This new element in the situation was the rapid progress through Parliament of the Local Government Bill, with its clauses relating to the transference, on April 1st, 1930, of the functions of Poor Law authorities to county councils. Accordingly, from the beginning of 1929 onwards the committee had before it a new and increasingly definite prospect that the London County Council would shortly be a local authority charged with the duty of providing and maintaining public accommodation for the sick poor in London.

The Hammersmith Scheme.

In studying the possibility of converting one of the public hospitals at that time controlled by boards of guardians, but now by the London County Council, the committee kept in mind the principle that any scheme in order to be practicable must present favourable conditions as regards time, money, and opportunity for the establishment without undue delay of a post-graduate hospital and medical school on a proper scale and at a proper rate. The number of such public hospitals is nearly thirty, and in considering a scheme on this basis special attention was devoted to six hospitals, and finally the choice was narrowed down to two—at Lewisham and at Hammersmith. In the end the Hammersmith Hospital, situated in Ducane Road, Shepherd's Bush, on a site of 14 acres, was unanimously chosen. This institution was built in 1905 and now has 400 beds, the in-patients averaging 356 throughout the past year.

The general advantages of a scheme based on the conversion of the Hammersmith Hospital are discussed in relation to finance (capital cost and cost of maintenance), and in relation to medical and administrative conditions. The hospital is readily accessible, and the capital cost of converting it to the new purpose, so far as can be judged, should not exceed £250,000. As regards the cost of maintenance of patients, the prospective annual charge at the Hammersmith Hospital, after its conversion, is estimated at £100,000, but some part of the charge at a public hospital would be recoverable from patients or persons liable to maintain them, and the balance would naturally and properly be a charge on the rates, in the same way as the present cost of maintenance of patients at this and other public hospitals. The population in the area served is already dense and is still increasing, and the committee is satisfied that abundant facilities for clinical instruction can be provided. Moreover, the London County Council would be in a position to assign cases to this hospital drawn from a total of 127,000 patients in the other public hospitals transferred to its control on April 1st under the Local Government Act, 1929.

The committee believes that the conversion of the Hammersmith Hospital into the British Post-Graduate Hospital and Medical School will not give rise to any difficulty as regards the position and responsibilities of the medical staff of the institution as it now stands. The five officers forming its resident medical staff became, on April 1st, members of the medical staff of the London County Council, and the Council could offer them similar appointments at other institutions. The consulting staff, 15 in number, are engaged on simple contracts, also *terminable*, as far as may be thought necessary, is a matter easily susceptible of agreement with the governing body of the institution.

It is recognized that the elaboration of a proper system of government for a British Post-Graduate Hospital and Medical School, based on the conversion of a public hospital, will not be free from difficulty. Provision would have to be made for the government, both of the medical school as an educational institution, and of the hospital as a public institution (of which the L.C.C. would be the governing body) for the treatment of sick persons. The working out of administrative details should, in the committee's view, be reserved until the scheme is not only accepted but *within sight of translation into effect*. A considerable part of the 14 acres is at present clear, and the site as a whole leaves ample room not only for building the medical school, but also for such additions to the number of beds and such expansion of the educational side of the organization as may be called for by growing demands upon it.

The committee therefore unanimously reports that it has drawn up a practicable scheme of post-graduate medical education centred in London by making the following recommendation:

> "That the British Post-Graduate Hospital and Medical School, comprising a hospital with 400 beds, a medical school, and residential facilities for post-graduate students, should be established, on a site which will permit of its future expansion as its services to the science and art of medicine and to the public are developed and recognized, by means of the conversion of a public hospital, the Hammersmith Hospital, in which the 400 beds initially required are already available. The residential facilities for students should be provided in part at the hospital, but mainly at a separate hostel in the medical and social centre of London."

THE GOVERNMENT'S DECISION.

In order to ensure the realization of this scheme, the Government has decided to contribute from public funds a maximum capital sum of £250,000 for building and equipping the medical school, in addition to providing for annual grants towards the maintenance of the school through the University of London as a recognized school of that university on the lines already applied to comparable institutions of university rank. These contributions will be the taxpayer's share of the cost of the scheme.

The Government is in agreement with the view of the committee that the cost of maintaining the Hammersmith Hospital when it forms part of the British Post-Graduate Hospital and Medical School should continue to be borne by the ratepayer, by whom it would have to be borne in any event as part of the public hospital provision for the people of London under the Local Government Act. This contribution will be the ratepayer's share of the cost of the scheme.

The Government has not, however, felt justified in calling further upon the taxpayer as such to give financial support to the building of the proposed residential hostel. But, as was stated by Mr. Greenwood in reply to Mr. Chamberlain's question in the House of Commons on April 9th, the Government understands that an appeal will shortly be made to the public for assistance in the establishment in London of a residential institution, to be called "London House," for the use of students from the Dominions not only in medicine but in other arts and sciences. Such an institution would, in the Government's view, secure the object aimed at by the Post-Graduate Medical Education Committee in recommending the provision of a hostel. The Government is in full sympathy with the movement, and looks forward with confidence to the success of the appeal when it is made, as crowning a scheme to which the taxpayer, the ratepayer, and the general public will be contributing their appropriate shares.

British Medical Journal.

SATURDAY, APRIL 19TH, 1930.

A NATIONAL POST-GRADUATE CENTRE.

"It is a reproach to London, as everybody must be growing tired to be told, that it has not got a post-graduate medical school worthy of it." These words, true enough nine years ago, are truer still to-day. London with its unrivalled material has never risen to the occasion. Before the end of the last century it became clear that the provision of facilities for post-graduate study was a pressing problem, and since then so many additions have been made to existing knowledge of curative and preventive medicine and surgery that the need for improving and increasing such facilities as exist has grown apace. Since 1919 the Fellowship of Medicine has done all that could be done with the means at its disposal; but, lacking a hospital and any kind of institute, this pioneer work has necessarily been, in large part, that of a bureau. Great credit is due to the Fellowship for its persistent efforts to keep post-graduate education alive in the largest city in the world.

In 1921 a committee under the chairmanship of the Earl of Athlone was set up by Dr. Addison when Minister of Health. The ground was rapidly surveyed and proposals were submitted, but the chief recommendation, for "a school attached to a hospital centrally situated in London devoted solely to post-graduate medical education, as a school of the University," has remained unfulfilled. In 1925 Mr. Neville Chamberlain appointed a second committee with a single clear-cut reference: "To draw up a practicable scheme of post-graduate medical education centred in London." This representative committee thus started at the place where its predecessor left off, and now at long last its report has appeared, and the scheme it unanimously puts forward is accepted and blessed by the Government. The contents of the report are summarized at page 745, and the statement by the Minister of Health will be found in our Parliamentary Notes. The "practicable scheme," finally arrived at, after weighing many alternatives, is for the establishment of a British post-graduate hospital and medical school comprising a hospital with 400 beds, a medical school, and residential facilities for students, by converting the Hammersmith Hospital at Shepherd's Bush. This modern institution, now under the control of the London County Council, has the 400 beds needed at the outset. To complete the scheme a fully equipped medical school will have to be built on the 14 acre site, and a hostel for graduate students established in central London. The Government, impressed with the urgency of the need and the feasibility of the plan, has pledged itself to contribute from public funds a capital sum of £250,000 for building and equipping the post-graduate school, and beyond this to provide annual grants towards its upkeep through the University of London. The cost of maintaining the hospital will fall, as at present, on the ratepayers. For the hostel money will have to be found by way of a public appeal.

A great step forward has thus been taken. A comprehensive and practicable scheme has been framed, a site and money have been found, and if the several parties to the undertaking work harmoniously with one goal in view, the capital of the British Empire will become in time a world-centre of post-graduate medical training. It is a great conception, and, when realized, it should have a vast influence in raising the standard of medical practice. The site chosen, though accessible, is not perhaps as central as could be wished, but it is fully large enough to contain the school buildings and to allow of additions to the existing hospital. Two matters of importance that will have to be gone into without delay are the services to which the present 400 beds should be allocated, and the staffing of the hospital; in particular, the arrangements for the teaching staff of school and hospital will need very careful and detailed consideration before the plans are finally settled. The Athlone Committee suggested that for the proposed centre of post-graduate education in London it would be advisable to enlist the services of clinical teachers from the undergraduate medical schools to a certain extent; but how this might be brought about has never been fully discussed. It is obvious that by one means or another the new hospital and school must enlist first-rate teachers of the highest standing. Nothing short of the best will do. Another appointment vital to the success of the scheme is that of the Dean of the school. This pivot position of organizer-in-chief should be held by a man who has had large clinical experience, and is thoroughly familiar not merely with the requirements of candidates for higher degrees and diplomas but also with the needs of general practitioners in this country seeking suitable refresher courses from time to time.

We are glad to note that an essential point made by the Athlone Committee—that the central post-graduate school of medicine, when established, should be a school of the University of London—has been recognized and accepted by the Government. And while on that point the hope may be expressed that the British Post-Graduate Hospital and Medical School may never be regarded as standing in isolation—a self-contained and self-sufficing unit. The London School of Hygiene and Tropical Medicine must, of course, be linked up with it; and affiliation should be effected between it and some of the special hospitals which for years past have been taking their share in graduate education. In this work of co-ordination the personality of the Dean of the new school will count for much. Under the administrative arrangements proposed by the Athlone Committee "the great special hospitals would be closely associated with the central hospital . . . and their post-graduate courses would be organized in connexion with the programme of work at the centre." Such appears to be the opinion also of the later committee, which says: "It is convenient to assume for the present purpose that post-graduate instruction for students in special branches of medical and surgical practice . . . will in the main be provided at hospitals other than the post-graduate centre itself; but that whatever external instruction can thus be arranged, the centre will not be complete unless it includes at the least as part of its own structure special departments for the study of tuberculosis, venereal diseases, ante-natal and post-natal conditions in women, and radiology." The provision of a suitable out-patient and casualty department at the Hammersmith Hospital is rightly held to be "an inevitable part of the cost of converting" that institution into the British Post-Graduate Hospital and Medical School.

The scheme now put forward and approved by the Government gives a framework into which a great

deal remains to be fitted, and the next stage will call for the exercise of tact and good will. We hope that in the working out of details those who have drawn the outline will give further service to the cause they have at heart—namely, "to secure that London should offer to the post-graduate medical students of Great Britain, the Empire, and the world, both the best instruction and the most cordial welcome which a great centre for the teaching and practice of medicine should provide."

THE BOARD OF CONTROL

THE Mental Treatment Bill came before the House of Commons on report on April 11th, but the debate had to be adjourned owing to hostile criticism of certain of its provisions by members on the Government benches, and only the first two clauses were under discussion. So far the debate has mainly centred on the retention of the Board of Control and its share in the administration under the bill; the clauses dealing with changes in its constitution have still to be considered. It will be recalled that the Royal Commission held that it would be undesirable that the Board of Control should lose its identity by being merged in the Ministry of Health, provided that the Minister had an effective general control over the policy of the Board. With this we heartily agree, and the Minister of Health may be congratulated on his resistance to attempts on the part of his supporters to alter the measure in a direction thus rejected by the Royal Commission. That body was satisfied that the criticisms to which the Board had been subjected were to a large extent ill-informed, and that where criticism was justified the cause was to be found rather in defects in the existing system than in any want of zeal on the part of members of the Board. In so far as the changes adopted in the bill tend to strengthen the Board by an increase of its staff and by a widening of its powers there can be general approval on the part of the medical profession. But whereas in other parts of the bill the tendency is to adopt a more enlightened and understanding and a less stereotyped and official attitude, even in some respects in advance of that recommended in the report of the Royal Commission, it is regrettable that in formulating the functions and constitution of the Board of Control both the Royal Commission and the framers of this measure seem to have been unduly inspired by bureaucratic ideals and to have failed to follow the best lights.

Under the bill the Board of Control promises to become a mechanical business department of the Civil Service, with its well-known methods and attributes so little admired by the outside public, and to cease to be an expert advisory body primarily concerned with problems calling for a living sympathy and a personal touch with those engaged in the actual remedial or organizing work or those themselves undergoing treatment all over the country. Unfortunately, this is the deliberate intention of the Government. Miss Lawrence, the Parliamentary Secretary, said in committee, "we desire to make the machine comparable to the existing machinery of the Ministry of Health and all other Civil Service departments. That is to say, we shall have the chief officials engaged mainly in Whitehall . . . the organization of the Department of Public Health will be brought into lines very completely resembling the other main departments of public health," and again, "we desire to make this a department modelled on the perfectly familiar lines of Civil Service administration, the senior officers mainly at Whitehall, with their assistant officers going round the country, and with their inspectors also going round the country." Surely this is a deplorable ideal to set up in relation to a problem such as the House is dealing with. This is indeed "bureaucracy" where it is not wanted. It seems, too, to be based on a misapprehension of the present mode of working of the Board. Miss Lawrence spoke as though all the affairs of the Board were conducted by the chairman and one member of the Board, ignoring the weekly meetings of the Board as a whole. Be that as it may, under present arrangements the senior members of the Board have direct knowledge of the persons and circumstances they are dealing with; under the new plan the Board is to be "engaged mainly in Whitehall." The senior Commissioners will rely for their knowledge on reports from a subordinate grade of visiting commissioners and inspectors. What sort of relations can develop between those in charge of institutions and doing the actual technical work on the one hand and such a body as this on the other, with the members of which the former may have no personal acquaintance and access to whom will be through a subordinate body of officials? What kind of intimacy with the problems and difficulties of the work will such a body be able to acquire? How can it avoid the dead touch of officialdom?

A similar bias seems to sway the Government in its attitude towards the amendments put down by Dr. Fremantle, which propose a larger medical element in the Board and to permit the inclusion of lay members who would bring their experience and services to the work without remuneration and so without expense to the public. The proposal to include at least two medical practitioners in the Board, one acquainted specially with medical administration and one representative of medical science, requires no special recommendation to those who adopt the modern attitude towards the whole of this question as primarily a medical one. What we want to get rid of is Miss Lawrence's idea of the need for a hierarchy of standard pattern and procedure. The Royal Commission expressly stated that the Board of Control has discharged its duties in a manner deserving of great commendation. Yet the Minister, in opposing these proposals as to personnel, proclaimed that the bill is a deliberate attempt to get away from the existing Board. It would seem that he is not content to remedy the defects in the present machinery, but wishes to remove those who have well and faithfully discharged their duties. Had the framers of this measure looked further afield they would have found that where in method and outlook psychiatry is most advanced, as in America—the impressions derived from a visit to which country were so well described by Dr. Mapother in his paper read last week before the Section of Psychiatry of the Royal Society of Medicine—there also are found the greatest elasticity and freedom from bureaucratic methods as well as full reliance on medical direction and control. But nearer home it is only necessary to look at Scotland, where a high standard of development in psychiatric organization is associated with the least possible pressure of formal officialdom. Let us hope that even at this late hour something may be done to infuse into this part of the bill some of that spirit of modernity and elasticity which illumines its other provisions.

THE BUDGET.

THE Chancellor's annual account of his stewardship of the nation's finance over the past year and of his proposals for the coming year deservedly attracts almost universal interest. Much of the attention is no doubt due to the popular appeal of the dramatic element in its closely guarded secrecy and in the gigantic amounts of money involved as well as to the occasional hopes and more frequent apprehensions that post-war Budgets have aroused. A less obvious reason for such interest lies in the fact that each Budget marks a definite stage in the development of the national financial scheme, and in doing so cannot fail to affect taxation for many future years. Presumably financial policy can be shaped by a series of annual remissions all directed to one purpose, but in practice such opportunities very rarely come to a modern Chancellor, and the shaping of policy is in fact effected by impositions rather than by remissions. As Mr. Snowden has proved for himself this year, a tax which is personally obnoxious may have to be retained—at any rate for a time—because he cannot dispense with its immediate pecuniary results. Circumstances very often put an additional restriction on a Chancellor's freedom of action. When additional money is required it is usually required at once, at least well within the financial year which has started by the time he puts forward his proposals. If new machinery of taxation is required it cannot be set up until the scheme has been approved by Parliament, and even then the wheels will probably move with a good deal of friction and with exasperating slowness for some months, and possibly—as in the case of the Lloyd George land duties—encounter legal and other obstacles which prevent its progress. There are indications that although Mr. Snowden's immediate problem was of such a magnitude as to absorb all his available resources, he has not been unmindful of the desirability—from his political standpoint—of commencing some tentative provision for the needs of next year. The position of a Chancellor who finds that a continuance of taxation on the present basis will produce a deficit next year of £42,264,000 is far from enviable. True the position is not really as bad as that because of the petrol tax provision in anticipation. That fund stands at about £16,000,000, but even when that—less some provision for 1931 and 1932—is brought in, the deficit approaches £30,000,000. Mr. Snowden proposes to discard the remains of the betting tax and to allow the safeguarding duties to expire automatically during the year. These duties are not to be confused with the more important McKenna duties, which are retained, but with the sword of Damocles suspended over their heads. Obviously the raising of an additional £30,000,000 of taxation in the current financial year places the Chancellor in the difficulty mentioned above. the sum is too great to be dealt with by setting up a new tax, even if some ingenious mind could devise one which Parliament could be induced to accept. Compelled to follow the trail blazed by his predecessors, he has turned his steps to the income tax. Probably Mr. Snowden's well-known reputation as a determined supporter of direct taxation will have reduced the surprise if not the chagrin of those taxpayers who in the aggregate will have to find this year the £21,000,000 additional income tax and the £7,500,000 additional super-tax which the increase of the standard rate to 4s. 6d. in the £ and the proposed adjustments of the surtax rates are designed to bring into the Exchequer. By these increases, coupled with increases in the scale of the death duties, practically the whole of the gap between anticipated expenditure and anticipated revenue is closed. The small increase in the beer duty is in comparison negligible, especially as it seems designed not to raise the price of beer to the consumer. By means of a modification introduced into the graduation scheme, the smaller income tax payers will be compensated for the increase in the standard rate. At present each taxpayer has a portion of his income free from tax—the amount so free depending on marriage, the number of children, etc.—and pays 2s. in the £ on the next £225. In future that "slice" of income will be £250 and will still pay tax at 2s. in the £. Obviously some taxpayers will be better off under the new scheme, and all will receive some compensation. As an illustration it was stated that, assuming the whole income to be "earned," an unmarried person will pay no more unless the income exceeds £582, and in the case of a married man with three children the corresponding limit is £882. To those we may perhaps add the example that a married man with two children in receipt of an earned income of £1,500 will pay an additional £14 thereon. The sum may not seem large in comparison with what such a taxpayer is already liable for, about £160, but it is one the payment of which cannot be made without additional drain on those savings which the "earners," from the very nature of their income, especially desire to make. Towards the close of his speech Mr. Snowden announced that he was laying plans for the setting up of a scheme for securing in future years some portion of the enhanced value of land created by the community; presumably he had in mind more particularly those outlying lands near large urban areas which improved public transport facilities are bringing into the building estate market. The introduction of the necessary bill at a later date may cause an amount of political excitement and argument that will put in the shade the more sober comment on the present Budget proposals. These, as so often is the case, will probably be accepted in the spirit in which the average British citizen makes the best of a bad job, doing his duty as a taxpayer without fuss or fury, thankful that it is no worse, and hoping, though faintly and without much real expectation, for better things in years to come.

PUERPERAL INFECTION IN INSTITUTIONS

IN a recently issued report on puerperal infection in maternity hospitals[1] Dr. A. S. M. Macgregor, medical officer of health for Glasgow, describes, and inquires into the causes and effects of, three outbreaks of puerperal sepsis that have occurred in late years in Glasgow maternity institutions. In the first outbreak (November, 1925) there were ten cases of puerperal fever and two of erysipelas, in the second (from February to June, 1928) there were fifty-four cases of puerperal sepsis representing 19 per cent. of the 289 women delivered within that period; and in the third (occurring between April and May, 1929) there were six cases of puerperal sepsis. The three outbreaks were severe in character, rapid in their spread, and in relation to the number of patients exposed to risk, extensive in their incidence. It was not always easy to determine how the infection was introduced and to follow the exact sequence of events, but there was enough evidence to show that a specific infection is likely to spread fairly easily under the average conditions obtaining in maternity institutions. On the other hand, the history of a year's experience of the incidence of puerperal infection in a small institution of twenty beds, where eight definite cases occurred without any grouping suggestive of case-to-case infection, or immediate transference of infection, points to the occurrence of cases of septic infection which, if recognized and promptly isolated, do not apparently give rise to other cases. The two administrative problems

[1] Edinburgh: H.M. Stationery Office. 1930. 9d. net.

are to keep infected parturient women out of hospital wards, and to prevent the subsequent spread of infection among other patients. As far as the first problem is concerned, the difficulty is to find an effective criterion of presumed infection. Dr. James Young of Edinburgh has suggested that the "clean" or "booked" case untouched prior to admission should have its own institution, and that the "suspected" case—namely, the case that has been subjected to certain kinds of intervention before admission—should be provided for in a different institution. According to Dr. Macgregor the inadequacy of this proposal is in the fact that cases subjected to manipulative intervention do not necessarily become septic, while in others infection may occur after a single vaginal examination, or even if there has been no intervention at all. It is, he believes, doubtful whether a water-tight administrative system based on segregation of patients in different institutions in accordance with the degree of intervention before admission, would be a practical or even a satisfactory way of meeting the difficulty. The methods adopted for the prevention of the spread of infection from patient to patient will depend on the view that is taken of the mechanism of propagation. In the largest of the three outbreaks recorded in the report under review the infection continued and recurred over a long period, in spite of the vigilance of the staff and the observance of all the obvious precautions. There was therefore every reason to believe that the transmission of the disease was due, not to some temporary or accidental defect of technique, but rather to some more continuous and radical cause. Dr. Macgregor's own conclusions are, that propagation occurs more probably by way of the hands of the attendants, or by instruments, swabs, dressings, and utensils, than by actual infection of the staff and their conversion into carriers of the specific organisms; he agrees, however, that it is reasonable to assume the latter mode of infection in some cases. Granted this view of the mechanism of propagation, the practical problem is whether the details of the conduct of labour in institutions are capable of improvement, and whether standards of management are sufficiently high to reduce to a minimum the occurrence and spread of septic infection. Whatever view may be held about the practicability of separating "clean" from "suspected" cases, it is obvious that in both groups the chances of case-to-case transmission of infection must be rendered as slight as possible. The very fact that the introduction of infected patients, or a patient likely to become septic, into a maternity hospital is generally held to be dangerous, is in itself a criticism of the technique at present employed, and suggests the need for reconsidering the methods of conducting maternity cases so as to raise the average standards to a point where the chances of infection are reduced to a minimum. It may be noted that in the outbreaks recorded by Dr. Macgregor there was no conclusive evidence of a relation between the presence of haemolytic streptococci in the throats of the nursing staffs and the incidence of infection. On the other hand, the cases recorded by Mr. W. W. King in his paper on throat infections and puerperal fever (*British Medical Journal*, March 22nd, p. 533) suggests that there is at least a prima facie case for the existence of such a relation in certain epidemics. Much further investigation will be necessary before all the factors that may be concerned in the spread of puerperal infection are discovered. It may be, as Dr. J. Parlane Kinloch suggests in an introduction to the report under review, that even the precautions proposed by Dr. Macgregor and Mr. King will be found inadequate, and the solution of the problem will demand in addition drastic changes in the administration, size, and arrangement of maternity hospitals.

TROPICAL DISEASES EXHIBIT AT ANTWERP.

THE Antwerp Exhibition will be opened by the King of the Belgians on Saturday, April 26th. The Tropical Diseases Section, in the British Government Building, has been organized under the auspices of the Exhibitions Branch of the Board of Trade, and is under the direction of a committee, of which Major-General Sir Wilfred Beveridge is chairman. The exhibit has been designed to impress upon the general public the importance of knowledge of health matters to those who live under tropical conditions. It also depicts certain dangers and the means by which they may be combated. A complete outline of thirteen important tropical diseases is presented by means of serial illuminated pictures, illustrating the causation, manifestations, treatment, and prevention of each disease. Above each series are placed enlarged photographs of work which has been carried out in connexion with the disease under consideration. Above these photographs are illuminated statistics showing the beneficial results to the community of such preventive treatment. The organisms responsible for various tropical diseases—protozoa, helminths, and bacteria—are demonstrated by colour photomicrography in six specially constructed viewing cases. Some of the diseases are dealt with in greater detail in six cases prepared and lent by the Liverpool School of Tropical Medicine, and several excellent wax models of the insect vectors of diseases are shown. Enlarged photographs have been prepared of men who have laid down their lives in the investigation of diseases prevalent in tropical countries; this exhibit indicates the special dangers attaching to research work in yellow fever and typhus. A model of the new London School of Hygiene and Tropical Medicine, taken in conjunction with the Liverpool School exhibit, emphasizes the fact that the importance of education in tropical medicine is recognized in this country. The care of those suffering from tropical diseases is largely in the hands of the Seamen's Hospital Society, which has prepared an exhibit illustrating the admirable work done by their hospitals. Two small historical exhibits are shown dealing with plague and leprosy in olden times. In the "Manson" exhibit the memory of the "Father of Modern Tropical Medicine" is honoured; to him and to Joseph Chamberlain the country is indebted for much of the progress that has recently been made in tropical medicine, evidence of which is displayed vividly at Antwerp. The Wellcome Museum of Medical Science has been responsible for the detailed organization of the whole exhibit, and also for the preparation of all transparencies, photomicrographs, and statistics.

CARCINOGENICITY OF OILS.

THE investigations carried out under the auspices of the Manchester Committee on Cancer on the carcinogenic factors in mineral oils, and on the possibility of manufacturing non-cancer-producing oils of adequate lubricating power are still proceeding, and in addition studies are being made of the cancer-producing properties of some animal and vegetable oils. We are glad to learn from the committee's report for the year ended October 31st, 1929, that two of the largest oil-producing companies in the world have recognized the importance of work designed to discover a safe lubricating oil at reasonable cost, and are now assisting the committee's scientific staff in its investigations. During the past twelve months tars have been prepared with the temperature of the furnace tube ranging from 500° to 950° C., in order to ascertain at what temperature carcinogenic compounds are formed in commercial tar and shale retorts. From studies of the relative activity of tars so obtained it appears that carcinogenic compounds begin to be formed between 500° and

to 300° C., and that the maximum yield is at a temperature between 800° and 900° C. In the course of earlier work, recorded in our issue of June 15th, 1929 (p. 1093), the scientific staff succeeded in preparing a pure synthetic tar containing the carcinogenic principle in such concentration that a 5 per cent. solution was more effective in producing cancerous growths than shale oil, the most dangerous of all commercially used oils. By continued investigations on the same lines it has now been able to prepare tars which are at least 100 times as powerful as shale oil. Furthermore, it is trying to determine the chemical constitution of a few apparently pure, or almost pure, compounds that have been isolated from such tars. In the course of studies designed to discover the effect of increasing the *frequency of application of carcinogenic* agents, it has been found that if the number of applications made each week is increased from two to five, tumours appear more quickly, and their incidence rises considerably, the rise being relatively greater the weaker the agent under investigation. Thus it appears that the carcinogenic potency of shale oil is increased approximately fourfold, and of natural petroleum oils about fifty-fold, by increasing the number of applications made each week from two to five. Such findings suggest that the carcinogenic activity of petroleum oils is much nearer that of shale oil than had previously been imagined. Applying their standard test for the determination of carcinogenicity, the scientific staff found that olive oil, neats-foot oil, and sperm oil were non-cancer-producing. They have reason to believe, moreover, that natural skin fat is an important factor in the prevention of experimental cancer. Thus, if lanoline—a natural animal fat—is applied to the skin in the interval between synthetic tar applications, the development of tumours is substantially delayed. If it is applied twice as often as shale oil cancer does not appear, but if the applications are alternate the protection afforded by the lanoline is much less marked. Yet another of the committee's investigations concerns the amount of sulphuric acid necessary to produce detoxication of oils, and under its auspices work is being done to ascertain the minimal amount of acid that can be used safely to render an oil harmless.

THE CAMBRIDGE UNIVERSITY APPEAL.

THERE must be few old Cambridge men who do not look back to their university days as some of the happiest in their lives. Therefore, when their Alma Mater pleads for assistance in extending the educational facilities she offers there can be little doubt about the response of her sons. A scheme has been prepared for providing a new university library, and for endowing some of the scientific studies fundamental to agriculture, medicine, and the health and development of the Empire and its industries. The scheme will cost no less than £1,179,000; but in 1928 the International Education Board of New York (founded by John D. Rockefeller in 1923) made the magnificent offer of £700,000 towards the scheme, provided that the university obtained £479,000 from other sources, and that the scheme was treated "as a unit." Towards this sum the university has managed to provide £250,000 for the library; the Ministry of Agriculture and the Empire Marketing Board have promised £84,000, and the Royal Agricultural Society £1,000. A committee, with Lord Melchett as chairman, has raised £53,000, and the Cambridge University Association has collected £21,000. The balance still required is therefore £70,000, and towards this senior resident members of the university and the staffs of Girton and Newnham have promised £10,000. An appeal is now addressed to non-resident Cambridge men to make up the deficit of £60,000, so that the munificent benefaction of the International Education Board may be earned. In addition to the provision for the university library, for agriculture, and for physics, the scheme contemplates endowment for the study of biochemistry and biophysics, of mycology and bacteriology, of physiology and of zoology. The appeal claims the attention, therefore, of all Cambridge medical graduates, who cannot fail to be willing to contribute, according to their means, towards wiping out the deficit. The Cambridge Graduates' Medical Club, of which Sir Humphry Rolleston is president, passed a resolution, on March 27th, expressing entire sympathy with the objects of the appeal, and commending it to the notice of all members of the club. Contributions should be sent to the Treasurer of the University, University Offices, Cambridge.

METHYL CHLORIDE POISONING.

RECENT reports of cases of methyl chloride poisoning[1] due to escapes or leaks in domestic refrigerator systems have suggested the possibility that in other such cases the diagnosis may have been missed. The 29 cases, with 10 deaths, that occurred in Chicago two years ago were all at first attributed to food poisoning[2]; in a further series of 75 non-fatal cases reported by Dr. H. M. Baker in the issue of the *American Journal of Public Health* dated March, 1930, the symptoms of poisoning were believed to be due to influenza. The individuals composing this series were workmen employed either in the manufacture of refrigerators, generally in ill-ventilated situations, or in attending to them in houses, stores, etc. Vertigo, staggering gait, drowsiness, ptosis, visual disturbances, nausea accompanied often by vomiting, and insomnia, were prominent; and, the gas being excreted slowly, its effects were cumulative. To render the use of methyl chloride foolproof Dr. Baker suggests that it is necessary to have safety devices not depending for their efficacy on the co-operation of the workmen, who refuse to believe that an inodorous gas can be dangerous. In the same issue of the *American Journal of Public Health*, Messrs. Connolly, Claffy, and Acherly, of the Department of Health, Chicago, make straight for the human factor complicating the problem: "People have taken toxic gases into their homes without question, because they have felt that the makers of the equipment would not knowingly expose the public to undue danger." On this act of simple faith they make the laconic comment: "All refrigerators in common use are toxic." The ideal solution, they suggest, would be to find a non-toxic refrigerant that could be used at the temperatures and pressures desired. They add, however, that "the discovery of such a refrigerant is not likely to occur in the near future because all gases, except the mixture we call air, are toxic in some concentrations." After describing the difficulties of control, they conclude that the greatest safety would lie in placing the system containing the refrigerant inside a second gas-tight system ventilated to the outside air. The widespread extension of mechanical refrigeration as a method of preventing putrefactive changes in food is creating new and serious problems that are worthy of close attention on the part of public health authorities.

In our advertising columns this week will be found an advertisement for an Assistant Medical Secretary to the British Medical Association. Applications must be received not later than the first post on Monday, May 12th, and the Council will proceed to election at its meeting on June 4th.

THE annual oration before the Medical Society of London will be delivered on Monday, May 12th, by Sir Arthur Keith; the subject of the oration is "Modern medicine and evolution."

Nova et Vetera.

THE EARLY HISTORY OF THE MANCHESTER MEDICO-ETHICAL ASSOCIATION.

BY

ROBERT GIBSON, M.D.,

PRESIDENT OF THE ASSOCIATION.

My review of the Manchester Medico-Ethical Association extends from the foundation up to 1882. It was founded on October 28th, 1847, and is the second oldest medical society in this city, the Manchester Medical Society having been founded in 1834. The objects of the association were the same then as to-day—namely, to maintain the honour and interests of the medical profession and to promote good fellowship among its members. On foundation day seventy-three gentlemen became members by act of signature, which, considering the time, was a large membership.

It was the first society of its kind in the country, and was, during the next few years, followed by ethical societies in many parts—namely, Macclesfield, Rochdale, Liverpool, Salop, Halifax, Cork, Belfast, and even as far away as Australia. From these various places the secretaries received requests for a copy of the rules in force in Manchester to help guide them in the formation of their societies.

It is difficult for us to realize what practice was like in those early days, so it is difficult to understand the activities of a society such as ours if judged by present-day activities. The Medical Act was not passed until 1858, and there was no register of medical men until 1859. The result was that many who laid claim to the title of surgeon or physician, or both, had no qualification for assuming such a title. It will be evident, then, that quacks flourished, and this society spent much time and money in trying to combat the evil of quackery. A solicitor was retained by the society to guide it in its efforts against quackery, and prosecutions were undertaken, sometimes with, but many times without, success. Reference to the daily papers of those times gives one an illuminating idea of the blatant and ridiculous claims of these quacks. Members of the medical profession, and of this society in particular, were forbidden to meet such quacks in consultation, but the fact that one of the officials of this association had to be asked to resign because he continued to meet them shows that they had a fairly strong hold on the public.

This society did all in its power to fight the evil, and in one report we read that: "The offensive and polluting nature of a class of quack advertisement appearing in certain Manchester newspapers having been brought to the notice of your committee, they have issued upwards of 2,000 copies of a very able address entitled *Hints to Newsreaders*." In this tract the public was urged to prevent the admission of such objectionable matter into their columns. Their attention having been brought to the subject by this movement, the proprietors of one of the journals made such alterations as, in some measure, mitigated the evil complained of. Chemists and druggists prescribed for and even visited the sick. In one report we find the committee remonstrating with the Manchester Board of Guardians because it had appointed a druggist to treat cases of diarrhœa without medical supervision. Pupils or apprentices in medicine practised before qualifying. These apprentices exhibited the testimonials received from their teachers, and even advertised them in the daily press.

Homœopathists as a class were looked on with great disfavour by our predecessors. A few of these homœopaths were qualified, but this society did not hold it to be ethical for any qualified man to consult with them. It was looked on as a form of quackery, and therefore taboo. This attitude was upheld by the *Lancet* and the *British Medical Journal* of the day. In the *Lancet* we read: "There can be no alliance between legitimate medicine and homœopathy. Any attempt to associate the two is fraught with danger to the public." The *British Medical Journal* wrote: "All honour to the Manchester Medico-Ethical Association for making so honourable a declaration. Indeed, ethical societies must declare before the profession that the man who meets the homœo-quack at the bedside shall be excluded from consultation by his brethren." Sir B. Brodie, one of the leaders in medicine, wrote on the same subject that medical men should never be induced by good nature, or any motive of self-interest, to appear to give their sanction to a system which they know to have no foundation in reality; to join with homœopaths in attendance on cases of either medical or surgical disease would be neither wise nor honest.

Such, then, was the attitude of this society in the fifties, but in the late seventies we find the subject of homœopathy again came up, and though a long and acrimonious discussion took place it was agreed that it was ethical to consult with any one if he were qualified to practise medicine. It was pointed out that no one body of medical men had any right to exclude another body of equally honest practitioners, even though they practised homœopathy, because medicine was not an exact science, and there might be good even in homœopathy.

Professional misunderstandings seem to have been more frequent in the early days than to-day. Indeed, it was one of the intentions in the formation of this society that such could be in great part overcome by bringing men together, as misunderstandings often arose from want of knowledge of each other, and frequently disappeared when personal relationship had been established without intervening gossip and busybodies. After the publication of the rules of this society men were in the habit of referring to them to settle their differences, and frequently the help of the secretaries was asked for in these disputes, mostly with the happiest of results. In cases that could not be settled by the secretaries the committee would form itself into a jury to try the case, but this only obtained after the aggrieved doctors had signed an undertaking that they would abide by the decision. Not only members, but even non-members, would carry their grievances to the secretaries for help.

A matter for which we must give the greatest credit to the secretaries was the compiling of a directory or register of medical men living within a radius of twenty miles of Manchester. I would have you ponder on the amount of work that this must have entailed. After printing it was circulated to all medical men within the area, and also to magistrates and registrars as a guide for them in their work. At least one supplement to this register was published, but compulsory registration became law with the passing of the Medical Act of 1858, and so relieved the secretaries from this onerous task.

During the first ten years of this association we find continued agitation to get the life assurance companies to pay for the medical reports on prospective clients. Previous to 1847 it appears that the client had to pay for the medical examination—a most unsatisfactory state of affairs. This must appear strange to men doing this type of work to-day. During the first year the secretaries circulated over a hundred companies in their endeavour to get them to pay for the report. Only fifteen agreed to pay, but most of them did not even reply to the circular. Then a circular was sent to medical men asking them to refrain from supplying the form without payment, but this procedure met with less response than the circular to the companies. A personal canvass of practitioners was next tried, but this also was unsatisfactory, as not half would agree to exact the fee from the company. However, the committee was not to be gainsaid, and by continued perseverance it obtained the condition which we enjoy to-day.

Another subject which came up for discussion by the committee was the appointment of medical officers to the hospitals or charity institutions of the city. In looking through one of the daily papers of the early fifties I came on an advertisement of several surgeons who were applying for the post of honorary surgeon to the Manchester Royal Infirmary. The letters of application were there as well as the testimonials given them by their teachers. This I was unable to understand until I found, in the life of Dr. Joseph Jordan, that medical officers were appointed by the governors. I take it that governor and subscriber are synonymous terms. Personal canvass was allowed, but as it was impossible to call on all the governors the help of the press was asked for, or, rather, paid for. So we find that on election day the male governors of the institution met in the town hall and the female governors in the

nation's room at the infirmary. A vote was taken, and the successful candidate was he who topped the poll. It is recorded that over 500 people voted at Dr. Jordan's election – there were four candidates. It is also recorded that the excitement was intense, resembling a parliamentary election. Dr. Jordan's expenses were £620.

It can be seen that such a method of appointment was not for the good of the institution, and as a result of representations it was changed, so that a subcommittee of the hospital, on which the medical men were represented, interviewed the candidates and made recommendation to the full board. In 1868 there was talk of appointing a medical officer of health for Manchester, so the town council was memorialized on the subject, but "it was feared that as the salary offered is no more than would be paid to a responsible clerk in a warehouse, it is likely that the benefit from the appointment will not be apparent for some time." In the next year we find that the appointment has been made, but the committee deplores the salary which is being paid. A medical officer of health for Salford was appointed the same year. In the later seventies provident dispensaries seem to have occupied a lot of the committee's time, but there are no records in the annual reports are not illuminating.

I have explained some of the ways in which this association looked after the interests of the medical profession of the day, but by far the greatest labour involved was that undertaken by the parliamentary subcommittee. Recently, when the rules of the association were under revision, a recommendation was made that this committee should not come up for yearly election as had obtained in the past. Our former esteemed member and colleague Dr. James Holmes strongly objected to such a course, holding that the parliamentary subcommittee was one of the most important committees and ought to come up for yearly election. After reading about the work of this committee in the past, I can quite see how difficult it was for an old member to recognize that the functions of such a body had been taken over in great part by the British Medical Association. Before 1858 this subcommittee was constantly in touch with members of Parliament and high officers of State regarding proposed medical reform. Thus we read in the 1852 report:

"Believing that it is the intention of the Government to bring before Parliament some measure of medical reform, it was thought expedient to petition the Home Secretary that in any bill introduced adequate provision be made for suppressing the practice of medicine and surgery by unqualified persons."

Such, then, was the main topic of controversy for the next six years. When eventually the 1858 Act was passed it was hailed with enthusiasm, but was not looked on as a perfect measure by any means. The power to prosecute the unqualified practitioner seemed to be there, but it was found, when tested in the law courts, to be sadly lacking in its scope. Consequently, after a few reverses the quacks, who had to a certain extent moderated their claims, became more bold, and it was not possible to do much with them. The disappointment of the qualified practitioner was keen, in particular that of the members of this society who had taken so much trouble, both by petition and personal interview with officials, to try and get a measure which would be of some help to them. The conditions under which they worked became so bad that a public meeting was held in the town hall in 1871 to protest against the Act. At the meeting Sir James Bardsley, president of the Medico-Ethical Association, presided. It was recommended (1) that there be one portal for admission to the profession; (2) that there be more direct representation of the general body of practitioners on the General Medical Council; (3) that a public prosecutor be appointed. It was felt that the association ought also to send forward a memorial, and this was done. The amending bill that was introduced was not considered satisfactory, so the whole profession rose against it, and it had to be withdrawn.

Another subject dealt with by this subcommittee was the question of death certificates. Before the introduction of the *Medical Register* death certificates were accepted from quacks, druggists, and others; with the setting up of the *Register* this was almost wholly altered. It also presented a petition to Parliament on the inadequate remuneration of the medical officers in the Army and Navy. This was entirely successful. The Vaccination Act, the Coroners Bill, the bill regulating the qualifications of pharmaceutical chemists, and other minor Acts came up for discussion. It is recorded that they met on eighteen occasions in one year. Court fees came up for discussion, and it is interesting to note the decision that mileage should be charged at the rate of 3d., but if the medical witness had to stay overnight there should be an extra charge of 2s. 6d. for a bed. The tariff was published in 1865, and from the first was a great success; the demand for it was so great that it ran through two editions very quickly. In the 1866 report the committee records its delight that, contrary to expectations, the profession had been almost unanimous in its commendation of the work. Telegrams were received from London asking for copies, to decide questions in the courts of law. Many instances have come to light where difficulties in the payment of fees have been smoothed over, and several of our new members have assigned the issuing of the tariff as their reason for joining us. The commendation from the medical press was general. The *British Medical Journal* wrote:

"We have now before us the result of their labours, and, on the whole, we think it highly creditable to their discrimination and judgement. We trust the tariff may be an assistance to our Manchester brethren in enabling them to obtain a due reward for their labours, and to avoid ruinous competition with one another."

From this short account of some of the past activities of our association it will be gathered that it was a very active body of earnest men, working together for the good of the profession of which we are members. Many of the benefits for which they strove we to-day enjoy; indeed, we look on them as commonplace, little thinking that our predecessors had to work hard to get them.

LOCAL AUTHORITIES AND HOSPITALS.

THE KING'S FUND MEMORANDUM.

Last year the King Edward's Hospital Fund for London published a memorandum on the relations between voluntary and municipal hospitals, with special reference to the situation caused by the passing of the Local Government Act, 1929, and some comment on it appeared twelve months ago in the *Journal* of April 6th (p. 659). That memorandum was based on the principle that in order to secure the most efficient service for the sick there should be co-operation, and not competition and overlapping, between the rate-supported and the voluntary hospitals. The latter are an essential factor in the hospital service of this country, and co-operation is required not merely in respect of the maintenance of the voluntary hospitals, but for the sake of the efficiency of those which are maintained by the councils of counties and of county boroughs.

It is therefore important that all those concerned in the management of voluntary hospitals, and all members of local authorities responsible for council hospitals, should fully appreciate the nature and extent of both the old and the new powers of local authorities relating to the provision of hospital accommodation. As a help towards this the King Edward's Fund has now issued a "Memorandum on the powers and duties of local authorities in the matter of hospital accommodation under the Local Government Act, 1929," which has been prepared by Mr. A. M. Trustram Eve. It is an important document, which should be carefully studied by all those for whom it is intended. It sets out in one of its sections the administrative requirements of the Act of last year with reference to the exercise of transferred Poor Law functions, and to the survey which the Act requires county councils to make as to complete provision for dealing with infectious diseases in their areas; but these matters have already been explained so fully in our columns that they need not be further referred to here. The memorandum sets out the legal position with reference to the powers and duties of local authorities for the provision of accommodation for the sick, the recovery of the cost of maintenance and treatment, and the exercise of the powers of providing hospital accommodation by payments by local authorities to voluntary hospitals and other institutions. In each

Belgium.

[FROM OUR CORRESPONDENT.]

Reform of the Medical Curriculum.

In the course of its consideration of proposed legislation to regulate the various academic degrees, the Chamber of Representatives approved a series of changes in the medical curriculum, which is now to extend over a minimum period of seven years. The first three of these will be devoted to the study of natural science and preliminary medical subjects, including anatomy, embryology, histology, physiology, and physiological chemistry. Students proposing to graduate in medicine, surgery, and obstetrics will devote the last four years to clinical work, certificates of satisfactory progress being required before admission to the four examinations which are part of the programme of this period. One year is ordinarily to be spent in a resident appointment in a hospital; failing this, special certificates are required of attendance during four months each at clinics of each of the three principal subjects of medicine, surgery, and obstetrics, and also at one or more of the clinics dealing with accessory subjects. The whole of this attendance at clinics must extend over twelve months at least, no more than two being attended simultaneously, and medicine and surgery being studied during different parts of the year. For the licence in dental science similar preparatory work has to be undertaken in natural science and medical subjects; this is followed by two years devoted to general and special pathology, pharmacology, and dentistry. Candidates for the higher degrees in medicine or dentistry have to present a thesis embodying research, which is eventually discussed with a panel of examiners; they have also to deliver an address on some subject chosen by the examiners. Women are eligible for academic degrees and enjoy the full privileges attached to them, with the exception of certain public duties from which they are precluded by the law or by regulations.

Insanitary Housing.

A ministerial circular has been issued calling attention to the law relating to the sanitary measures required in the case of unhealthy dwellings. The Government desires burgomasters to arrange for joint action by private owners and societies controlling cheap residential property in order to bring about the progressive abolition of insanitary housing. Among the police duties entrusted to communal authorities by law is the maintenance of healthy conditions in public places, streets, and buildings. This includes such preventive work as the adoption of all necessary precautions against accidents and the scourge of epidemic diseases. From the point of view of hygiene, the numerous steps which can be taken by these authorities comprise the cleansing of the streets and dwelling places, removal of rain water and factory drainage, suppression of the sources of infection, the filling up of ditches and pools, and the prohibition of a variety of conditions which endanger the public health. The legislative details involved can be included, as a rule, in general communal regulations, but it is also strongly urged that the more important ones shall be made the subject of definite enactments appropriate to the special needs of particular localities. Societies concerned with the detection of unhealthy homes are required to act in close collaboration with the communal authorities, to concert active measures, and to submit only such comprehensive proposals as take account of all contingencies.

Campaign against Buboes in the Congo.

Dr. Van Nitsen has provided a scheme for an anti-bubo campaign on the following lines. A travelling hospital, under the charge of a doctor, will be established at the centre of the area to be dealt with. The staff will be sent from it in all directions, so as to get rapidly into contact with the whole of the population. Careful examination will be made of the natives, and anyone who shows signs of lesions or has a suspicious history will be subjected to treatment. He will then receive a metal disc carrying a serial number corresponding to one in the register, where will be entered the medical history and the treatment undertaken. Severe cases can be removed by means of the travelling hospital. The first course of treatment is directed to patients with contagious wounds, in order to abolish the [illegible] their infecting others. The hos[illegible] travels to a second area, and [illegible] returning to the first one after three months. In this way it will be possible to detect any persons who have escaped the first investigation, and to complete the treatment of others. All the areas will be visited in turn every six months, and thus infected persons will be cured by successive courses of treatment.

Massage Training for the Blind.

As the result of concerted action by the four Belgian universities, there has come into existence, under the control of the State and of members of the medical profession, a central school in which specially selected blind men and women will receive a complete course of training in massage. A first-class diploma, valid for the whole country, will be awarded both to those who have their sight, and also to blind students at this school, if they acquit themselves well during their training and obtain a minimum of 50 per cent. marks in an officially organized examination, which will be conducted by representatives of the various organizations interested. There is also to be set up an association of certificated blind practitioners of massage, similar to the one in England, and responsible for the supervision of these licentiates, their progress, and the defence of their interests generally. It is highly probable that this new departure will receive the support of the public authorities, for it will enable a number of blind persons to become useful and independent citizens, and will, consequently, reduce the financial and social obligations of the State and of the communes.

Belgian Association of Medical Women.

A section for medical women has been established in connexion with the Belgian Federation of University Women, with an initial membership of sixty. It is affiliated to the International Association of Medical Women, which has the three following objectives: (1) to provide for the co-operation of medical women in questions relating to international hygiene; (2) to obtain for medical women in different countries possibilities of communicating with each other, and of advancing their mutual interests throughout the world; (3) to give to medical women opportunities of meeting at fixed intervals to discuss problems concerned with the health and well-being of humanity.

Scotland.

Sir James Mackenzie Memorial Lecture.

THE first James Mackenzie Memorial Lecture, under the auspices of the James Mackenzie Institute for Clinical Research at St. Andrews, was delivered on April 8th by Professor John Hay, M.D., of Liverpool University. Provost Boase, St. Andrews, presided. Professor Hay considered that James Mackenzie would rank with Sydenham, Stokes, Graves, Addison, and Bright. Since his death in 1925, it had become possible to estimate his influence to some extent. The quest of his life was to understand the mechanism and prognostic significance of symptoms. For that purpose he observed every patient carefully over many years, keeping detailed records and making frequent analyses of his findings. The significance of pain was a subject that occupied a great deal of his time and thought. The results of his study of the pulse were published in 1902, and this book, which formed a landmark in cardiology, made Mackenzie's reputation. His observations aroused much interest in Germany and in America. At the age of 54 he took up practice in London as a heart specialist. During the war he was asked by the Government to give his assistance in organizing a special branch of the medical service. It was manifest at the time that organic and functional diseases of the heart had not been clearly differentiated; thousands of fit men were being rejected at home and in France, and military hospitals were becoming congested with cases of so-called heart disease. The scheme devised by Mackenzie, in collaboration with Sir Thomas Lewis, has done much to

spread a more accurate knowledge of disorders of the heart among members of the medical profession. In 1918 Mackenzie left Harley Street, and at the age of 65 began work in St. Andrews, where he founded the institute for clinical research that now bears his name. Mackenzie believed that future progress in medicine depended largely upon those who studied the symptoms of early phases of disease, and it was this belief that led him to give up consulting practice in London and to start the institute in St. Andrews.

Edinburgh Post-Graduate Courses in Medicine.

The programme of post-graduate courses to be held at Edinburgh during the summer of 1930, in connexion with the University and the School of Medicine of the Royal Colleges has now been issued. A course on obstetrics, gynaecology, and diseases of children will be held from July 14th to August 9th, it includes clinical midwifery and clinical gynaecology, obstetrical and gynaecological anatomy, physiology and pathology, diseases of children, child welfare, and ante-natal clinics. The fee for this course is ten guineas. A general practitioners' course will be held from August 11th to September 6th. This course will extend over four weeks, for which a fee of ten guineas is charged, the first or second fortnight may be taken separately at a fee of six guineas. It includes instruction in applied anatomy, clinical medicine, infectious diseases, clinical surgery, and clinics on gynaecology, diseases of children, diseases of the eye, diseases of the ear, nose and throat, and dermatology. There will also be afternoon classes on bacteriological diagnosis, morbid anatomy, radiology, ultra-violet ray therapy, etc. Concurrently with the latter a general surgical course will be given at similar fees. This course will include applied anatomy, general surgery, special instruction upon the diagnosis of renal disease, abdominal surgery and attendance upon surgical operations, surgical clinics, demonstrations of surgical pathology, radiology and similar subjects. Special classes for small numbers will be held upon such subjects as the pathology of the nervous system, vaccine therapy, medical chemistry, diseases of the blood, x-ray physics, etc. Attention is also drawn in the programme to some extended courses which are held during the summer, autumn, and spring terms, upon diseases of the throat and nose, ophthalmology, venereal diseases, surgical pathology, and clinical medicine and clinical surgery. Application for enrolment in the various classes should be made to the secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Gogarburn Institution for Mental Defectives.

The first two blocks of the Gogarburn Certified Institution for Mental Defectives, which is under course of erection by the Edinburgh District Board of Control, were formally opened on April 4th by the Right Hon. William Adamson, M.P., Secretary of State for Scotland. Colonel Young, chairman of the Edinburgh District Board of Control, who presided, said that the District Board of Control had purchased, in 1913 and 1926, the estates of Gogarburn and Kellerstain, extending to 419 acres. The present buildings, and much other work approaching completion, would be handed over to their successors. During recent years, a long list of cases had been awaiting treatment, and over 100 of the most urgent would be admitted to the present buildings. About 20 similar blocks would be erected to accommodate 1,040 patients. In paying a tribute to the work of the district board Mr. Adamson said that the present institution was really a collection of cottage homes, a striking improvement on the large forbidding prison-like structures of the past. The operation of the Act of 1913 for dealing with the problem of mental deficiency had been interrupted by the war and by the difficulties that followed it, but he thought that progress was now being made. The number of cases of mental defect must be ascertained at as early an age as possible. Town and county councils were provided by legislation with machinery for ascertaining mental deficiency, and this work would be divided among several of their committees. For example, the defective child in a special school would be dealt with by the education committee until it reached the age of 16, when it would come under the supervision of another committee. It was important that careful provision should be made in each case when the responsibility of the education committee ceased. Treatment in institutions, Mr. Adamson said, was not necessary in all cases, for many children after attending a special school could lead useful active lives in the community. The most urgent need in Scotland at present was additional institutional accommodation; its provision would remove one of the chief difficulties of the problem of mentally defective adults, who could now obtain a healthy happy home, where they would have a chance to develop themselves as far as their faculties allowed. Care in institutions would also prevent women who were mentally affected from having children which they were incapable of bringing up, whether these children were defective or normal. It would also save many men and women from misery and crime. He regarded the work of the Gogarburn institution as of the greatest national importance. The Gogarburn Mental Defective Colony is situated about three miles west of Edinburgh, and is the first colony in this country to be built under the Mental Deficiency Act of 1913. It will accommodate over 1,000 patients, who will be drawn from Edinburgh and the South-east of Scotland. Sufficient ground is available for ensuring proper segregation and for the employment of the inmates in agricultural and other outdoor pursuits. Every house in the colony, which is designed as a village, has accommodation for 50 patients, under the supervision of a housekeeper. The main entrance of each building is placed on the north side, thus allowing of unrestricted verandahs on the south. Four dormitories and two day rooms with kitchen and staff accommodation are provided. Special care has been taken to make the rooms attractive to the patients.

Election of Edinburgh University Chancellor.

At a meeting of the General Council of the University of Edinburgh, held on March 31st, a committee was appointed to recommend a candidate for nomination for the chancellorship, rendered vacant by the death of the Earl of Balfour. The election will take place on May 7th. Dr. Morgan, convener of the business committee of the council, referred to the late Lord Balfour's services to universities. Lord Balfour, he said, took an early interest in Edinburgh University, where he founded the Balfour Lectureship in Philosophy in 1895. On the death of Lord President Inglis in 1891 Mr. Arthur James Balfour, as he then was, was elected to the chancellorship, at the beginning of a period of great reform. The Universities (Scotland) Act of 1889 had just been passed, and the commissioners appointed under it were issuing ordinances that were remodelling the educational and administrative systems of the Scottish universities. By his services at that time, and during the thirty-nine years of his chancellorship, Lord Balfour had helped to consolidate the position of the University.

Smoke Abatement in Scotland.

The annual report of the executive committee of the Scottish Branch of the National Smoke Abatement Society for the year 1929–30 states that public opinion is now awakening to the importance of securing a purer atmosphere. During the past winter the weather of Glasgow and the West of Scotland was comparatively free from fog, and in consequence there was a low incidence of respiratory disease except during February, when fog prevailed. Observations were made by Mr. Harris, chemist to the Glasgow corporation, upon the amount of ultra-violet light reaching the city. If these records are continued they will form, it is thought, a useful index of smoke pollution, and will enable comparisons to be made with other parts of the country. Early legislation on the lines of the Public Health (Smoke Abatement) Act of 1926 is recommended for Scotland. The report also states that Scottish firemen are attending classes held by the society for instruction in the most economical methods of fuel combustion producing the minimum of smoke. Pure air, it is pointed out, is as essential to health as pure water, milk, and food, and may be obtained if reasonable precautions are taken.

England and Wales.

A Poor Law Hospital.

REDHILL Hospital, Edgware, though not one of the largest, is one of the newest, most fully equipped, and most completely organized, of the Poor Law hospitals. It was opened by Mr. Chamberlain, then Minister of Health, in December, 1927, having been planned on the most modern lines and built and equipped in the most up-to-date fashion by the Hendon Board of Guardians. It may now be said to be the chief hospital for the treatment of acute medical and surgical cases in its neighbourhood, and, together with the Hendon Cottage Hospital, supplies the needs of a large area. It has an extensive maternity department, with an ante-natal clinic. It makes large provision for dental treatment, for treatment by massage and radiant heat, and it has very active radiological and pathological departments. It is approved as a complete training school for nurses. The second annual report of the hospital has been issued by the Hendon Board of Guardians in the form of a pamphlet by Dr. J. Nissen Deacon, the medical superintendent. The pamphlet gives a very interesting account of the activities of the hospital during the year 1929, and includes well-arranged statistical tables showing the extent and variety of the work undertaken in the several departments and the results attained. There is a useful appendix of regulations relating to the admission of ordinary, paying, and maternity patients, the ambulance service, the visiting of patients, x-ray charges, and the training of nurses. This publication is particularly interesting and valuable at the present time as showing the kind of work that is being done in the best type of Poor Law hospital, and the way in which such a hospital is being used by patients and practitioners in its neighbourhood. It may usefully be noted by those who are interested in the problems raised by the transfer of the administration of institutions of this kind from boards of guardians to the councils of counties and county boroughs.

New Health Centre for Willesden.

The Minister of Health (Mr. Arthur Greenwood, M.P.) visited Willesden, on April 8th, to open the new health centre of the Willesden Urban District Council in the rapidly growing district of Stonebridge Park. Mr. Greenwood said that any local authority which set an example of progressiveness in public health service had his warm commendation. For many years Willesden had taken a serious view of its duties in this respect. It had looked after the two most important factors in the health of the race—namely, the well-being of the mother and of the child. He paid a high tribute to Willesden's indefatigable medical officer of health (Dr. G. F. Buchan), to whose annual reports he stood indebted. Dr. Buchan had rightly stressed the importance of the problem presented by maternal mortality. Motherhood was the most dangerous of occupations. It was not merely that 3,000 mothers lost their lives annually in child-bearing, but an uncounted number of those who survived suffered permanent incapacity, and this was probably reflected in the lives of children subsequently born. Whatever might be the cause of this persistent mortality, a good deal of it could be alleviated if the expectant mother would go to the maternity centre. Women were still too reluctant to take advantage of the specialized knowledge which was available. In Willesden, said the Minister, the service which had been developed was a credit to the locality, and the real value of the new clinic would be not merely in the treatment which took place in it or in connexion with it, but in what it stood for and the new attitude it suggested towards individual and communal health. In spite of many difficulties, some of them encountered in his own department—though before his own period of office—Willesden had pursued a definite and constructive policy, and while he himself might not always in the future agree with what Willesden set out to do, he would never question the outstanding sincerity of its authorities and their desire to serve their people. In some further speech-making, Councillor W. A. Hill, chairman of the urban district council, claimed that the new clinic was the "last word," at all events so far as small clinics were concerned; and Councillor William Bolton, chairman of the health committee, who said that the circle of health services in Willesden was not yet complete, announced that the council had taken over from the Middlesex County Council what had formerly been a hospital for small-pox cases, and this would be used as a maternity hospital, for women referred from the clinic and others needing hospital service.

The new clinic is a building in the Harrow Road, all on the ground level, with every department intercommunicating, and with space for extensions. It is designed to house all the multiple activities which constitute a health service, and there is spacious provision for ante-natal and maternity care, and for the regular examination of children from birth to school-leaving age. The other departments include those for orthopaedics, "artificial sunlight" treatment, eye cases, ear, nose, and throat cases, and dental examination and treatment. There is to be linked up with the clinic a service of consultants for further advice in difficult cases, and a hospital service where beds are necessary. The building includes a large reception hall, where health lectures are to be given. The equipment of the clinic, while not over-elaborate, appears to be efficient for the purpose of each department, and alike in the architecture and interior decoration there is a pleasing freshness and homeliness about the arrangements.

The Royal Institute of Public Health.

The congress this year of the Royal Institute of Public Health will be held at Portsmouth, from June 4th to the 9th. The scientific work will be arranged in five sections: State medicine and municipal hygiene; naval, military and air (including tropical diseases); industrial hygiene; women and children and the public health; and tuberculosis. The subjects to be discussed include: the reduction of preventable disease, national health and the Local Government Act of 1929, heredity in relation to the nation's problem of mental deficiency, problems of the sea-faring doctor, the health of the worker to-day, the voluntary worker in relation to the public health service, the slum child, and sun treatment in England. Arrangements are being made for visits to the Treloar Cripples' Hospital and College at Alton; King George's Sanatorium for Sailors, King Edward VII Sanatorium, Midhurst, Portsmouth dockyard, and the Isle of Wight. The congress banquet will be held at the Queen's Hotel, Southsea, on June 5th, and there will be a service in the cathedral on Whit-Sunday morning, June 8th. The usual arrangements are being made as regards reduced railway fares, and the sanctioning of the expenses of delegates from local authorities. Further information may be obtained from Dr. T. N. Kelynack, the Royal Institute of Public Health, 37, Russell Square, W.C.1.

The Midwifery Service.

The council of the Midwives Institute has set up a joint committee, consisting of representatives of associated bodies, with the object of securing united action and prompt decision in regard to measures for improving the midwifery service in this country. Members have been nominated by the Association of Inspectors of Midwives, the Association for Promoting the Training and Supply of Midwives, the College of Nursing, the Incorporated Midwives Institute, and the Queen's Institute of District Nursing. In a memorandum issued by the committee, agreement is expressed with the report of the departmental committee on the training and employment of midwives[1] so far as it relates to legislation in accordance with the proposals for a comprehensive and national maternity scheme. These proposals refer to medical attendance and examination during and after confinement, and to the responsibilities of midwives for ante-natal and post-natal care and nursing. The committee also agrees with the provision for professional service supplemented by maternity benefit, and with the recommendation that institutional arrangements should be made for confinement in special circumstances or for reasons of personal convenience, but it disapproves of any legislation transferring

[1] Report of the Departmental Committee on the Training and Employment of Midwives. H.M. Stationery Office, London. 1s. (See *British Medical Journal*, September 28th, 1929, p. 592.)

the control of the profession to a Government department, on the grounds that independency is essential to the maintenance of professional standards and necessary for the efficient operation of a national maternity scheme. In regard to the reorganization of a controlling body, it considers that the Central Midwives Board, or special body exercising control over midwives, should retain the duties connected with the training, penal work, examinations, and government of the profession, and that this body should continue to represent the Government, the local authorities, the Judiciary service, and the medical profession.

Ireland.

Poor Law Relief in the Irish Free State.

A JUDGMENT of pa[illegible] matters to Poor Law medical officers has recently been delivered by Mr. Justice Meredith, who held that persons who were destitute and permanently resident in the area were entitled, as a right to receive relief from the public rates of the Poor Law union in which they were resident. It has long been held that the decision of the Minister for Local Government and Public Health was final in complaints of the alleged refusal of relief to persons in a number of cases which came before the Dublin Union Commissioners. In giving judgment Mr. Justice Meredith said that the plaintiffs were the guardians of poor persons for whom provision had been made by the Act of 1847. It was the duty of the Commissioners as guardians, under the mandatory section providing for relief, to place the destitute poor either in workhouses, if there was room for them in the institutions, or upon outdoor relief; they were empowered to declare rates for the purpose. Costs were given against the Commissioners, who intend to appeal to the Supreme Court.

Alleged Illegal Detention in a Mental Hospital.

Mr. Justice O'Byrne recently made an order staying further proceedings in an action for illegal detention brought by a former patient against Dr. J. O'C. Donelan, resident medical superintendent, Grangegorman Mental Hospital, Dublin, on the ground that it was frivolous and vexatious. It appeared in the evidence that the plaintiff, Patrick Moore, had been detained in the hospital from May 6th to June 28th, 1927, in pursuance of a committal warrant, issued by the District Justice in the Dublin Metropolitan Court, and that this warrant had not been invalidated.

Correspondence.

THROAT INFECTIONS AND PUERPERAL SEPSIS

SIR,—I am indebted to Dr. James Young (April 5th, p. 665) for his valuable criticism of my paper on throat infections as an etiological factor in puerperal sepsis. It is satisfactory to find that he agrees with the proposition therein set out, even if he prefers to flirt with the subtle suggestion that the attendant's throat must have been primarily infected from some parturient woman. This supposition of the probable sequence of events is not supported by our observations in the wards for puerperal sepsis in the special block in connexion with, though remote from, the Joseph Hospital. There the incidence of haemolytic streptococci in the throats of the resident and nursing staffs is no higher than elsewhere.

Dr. Young makes a good point against me when he cites the low death rate in certain maternity hospitals as evidence that throat spraying and the so-called "antigenic infections" are not factors of importance in the etiology of puerperal sepsis. But too much can be made of it. The same type of argument was brought against the use of masks and gloves in operating theatres a few years ago, and before that against the use of anti-septics. It is so with every advance. In this connexion I am sincerely indebted to Dr. A. S. Garden for his timely contribution to the discussion, published also on April 5th (p. 655). An outbreak of puerperal sepsis due to haemolytic streptococcal infection was traced to a carrier nurse, and ceased immediately she was removed from the wards. Here is practical proof, from an independent source, of the danger and the remedy. One must account hospitals fortunate into whose midst fate has not cast a carrier.

Dr. Young has misunderstood my statements in regard to the incidence of haemolytic streptococcal infections in spontaneous and operative deliveries respectively. I see no reason for his presumption that some of the cases were admitted for sepsis and some for obstetric reasons. All the cases under review were sent into the hospital because they were septic, so that Dr. Young's faulty assumption has led him to the incorrect inference that I was comparing cases of different orders. My discussion concerned the quota of these septic cases (spontaneous and operative) which were infected by haemolytic streptococci. My inference from the type of labour preceding the onset of sepsis from this organism is clearly stated—"Handling is not of itself a factor in the spread of the disease"—that is, puerperal sepsis caused by haemolytic streptococci.

The figures, of course, bear no relationship to the incidence of puerperal sepsis in spontaneous as against operative deliveries in general. They refer to one type of delivery in reference to the type of labour in a series of cases of puerperal fever caused by different organisms—

I am, etc.,

W. W. KISO.

[illegible]

ANÆSTHETICS IN MIDWIFERY.

SIR,—I am loath to enter into the correspondence on the above topic, but I feel that the letter from Dr. Rowland in your issue of April 12th (p. 718) calls for comment. I presume that when Dr. Rowland talks about "slowing down and sometimes suspending the normal uterine contractions," etc., he is referring to chloroform as the anæsthetic; and, if so, he is undoubtedly correct. I would, however, if I had ever conducted a labour where gas and oxygen has been used for each pain, and a little ether added as the head is being born. I read a short paper on this method at the Annual Meeting of the British Medical Association in Manchester last year, and there pointed out that a labour conducted with this type of analgesia [illegible] anæsthesia for the delivery of the head entailed—so far as I could see—no risk to either mother or child, and in my opinion the pains were not slowed up, but when extra oxygen was given my impression was that they were accelerated. With added experience, I am quite convinced that the method I have described is at present the best means we have of alleviating the pains of labour—and there is no doubt in my mind that these pains should be alleviated. Surely we have advanced from the time when a lady of rank, one Euphame Macalzean, was charged with seeking the assistance of Agnes Sampson for the relief of pain at the time of the birth of her two sons, and was accordingly buried alive on the Castle Hill of Edinburgh!—I am, etc.,

H. EDMUND G. BOYD.

[illegible]

INJECTION TREATMENT OF VARICOSE VEINS.

SIR,—Dr. Criteell's observations (March 29th, p. 613) on pain after puncturing a vein are interesting, but he does not say how long after the puncture the pain comes on. In my own experience no pain is caused by the needle entering or perforating the vein wall; and since some time, from a few seconds to a few minutes, elapses while the vein is being emptied of blood before the injection is made, any pain arising from the puncture of the wall should be easily observed. Every care is taken to prevent contamination of the tissues by the solution, but sometimes, when the piston of the syringe is working loosely, a small quantity of solution might possibly get into the vein wall. if the skin does not wipe it off. No immediate pain has been noticed in these cases. The pain that Dr. Hector and I refer to and utilize begins very definitely a certain time after the solution is injected, and varies with its strength after dilution with blood. It does not seem to

have been noticed before, and certainly not utilized, and its observation has helped to convert a haphazard method into an orderly one.

In view of the fact that the use of sodium chloride is usually regarded as painless, it occurred to me to try it in solutions of greater strength than those generally employed. It is clear from these trials that the pain again varies with the strength of the solution. It is, however, usually less severe than the pain following injection of salicylate, and is of a different character. The sensation is more tingling than burning, and its distribution is less definitely localized. Both solutions may cause cramp-like pain. True cramp of the muscles is seldom seen, though forcible stretching of them eases the pain somewhat. Thus 25 per cent. and 30 per cent. saline are easily guidable in medium to large veins, and 20 per cent. saline is guidable in small to medium ones. Ten per cent. salicylate in any strength of saline over 15 per cent. is "on the strong side," and 2½ per cent. is too weak. A good average guidable solution for those who prefer saline to salicylate is 25 per cent. saline with 5 per cent. salicylate. From trials now going on it seems that in veins of comparable size, and always allowing as far as possible for any escape of solution into the deep anastomotic veins, 30 per cent. saline is "about as painful" as 20 per cent. salicylate, and 30 per cent. saline with 5 per cent. salicylate is "about as painful" as 35 per cent. salicylate. I agree with Dr. Crivelli that the risk of necrosis is greatly diminished with practice, a fact which somewhat limits the facilities for teaching the work to students.

If others would publish their technical details, giving in general the local characters and the sizes of veins, the strengths of solutions used, and the number of injections required for each case, it would be possible to arrive at an approximate standard solution and dosage for the painful but guidable method of injection.—I am, etc.,

Aberdeen, April 7th. G. H. COLT.

GEOGRAPHICAL DISTRIBUTION OF RHEUMATIC FEVER.

SIR,—In his recent Milroy Lectures[1] Dr. Alison Glover has advanced the hypothesis that rheumatic fever is a "specific infectious disease conveyed by a droplet infection." He makes, however, no reference to the geographical distribution of the disease. In the preface to the first part of the special report on rheumatic heart disease in children,[2] one of the proposals was that "further investigations" should be made of the geographical distribution of the disease. In the second report,[3] although this proposal is mentioned as one of the references, there is no further allusion to the subject. It might be thought that this reference was afterwards regarded as of no importance, but nearly all the books on medicine say something about geographical distribution, and that of Hirsch—published in 1886—has been much quoted on the subject. Dr. Reginald Miller[2] has stated that "there has been no recent inquiry into this question [of geographical distribution], and material for any accurate world map of rheumatism is probably not available." Dr. Carey Coombs[4] writes that "broadly it is found in temperate climates only," and adds, "the data on which a reliable opinion [of the geographical distribution] could be founded are not yet available."

May I point out that the geographical distribution of rheumatic fever may have a very important bearing on the ideas of the causation of the disease. If it was found that overcrowding, sore throats, damp houses, and houses near streams were common in those parts of the world where rheumatic fever did not occur, there might be occasion for the revision of some of the hypotheses that have been advanced as to the cause of the disease. Further, may I point out that I have given[5] a large amount of evidence to show that rheumatic fever does not occur in the Tropics, where the above-mentioned conditions are common. Overcrowding in houses and in schools, sore throats, damp houses, and houses near streams are not rare in the Tropics; on the other hand, in tropical latitudes there is hardly any water-borne sewage—until recently there was none—and no brown rats (*Rattus norvegicus*), save a few in some of the bigger ports. In temperate climates brown rats in a house are usually a sign of a broken drain; and I suggest that it will be found that a broken drain is the most common concomitant of rheumatic fever, though whether the rat or its flea is the carrier of the disease is a matter for investigation.—I am, etc.,

J. TERTIUS CLARKE,
late Medical Officer and Health Officer, Perak, F.M.S.

OESOPHAGEAL OBSTRUCTION IN CHILDHOOD.

SIR,—I should like to make just a few comments on Dr. Sheldon's reply (March 22nd, p. 568) to my letter published in your issue of March 8th (p. 467). I had suggested that, on the published details, there was considerable doubt about the diagnosis of some of the cases which he and Dr. Ogilvie had reported in their paper on this subject, and I hoped that he would be able to state that further facts were available in support of their diagnosis. Apparently this is not so, and he is content to rely upon the close similarity between the clinical picture of those cases which had a proved stenosis (shown post mortem) and those which had not. I feel sure he will agree with me that a similarity of symptoms does not necessarily denote identity of pathological findings. The symptoms of oesophageal obstruction from any cause are so constant that I should be grateful to him if he would tell me how he can distinguish between those due to congenital stenosis and those due to spasm or achalasia, even with the help of an *x*-ray examination. They must have a close similarity, or his colleagues at Great Ormond Street would not have fallen into the error of diagnosing some of his cases as cardiospasm.

Dr. Sheldon says he is "in complete agreement" with me "about the value to be placed upon a skilful oesophagoscopy." I place so high a value upon this procedure that I do not consider the diagnosis has been established until it has been carried out. I am glad he agrees with me, and I hope he will tell me how many of his cases were proved in this way.—I am, etc.,

London, W.1, April 7th. C. C. BEATTY.

DEATH DURING SPINOCAIN ANAESTHESIA.

SIR,—Our debt to Mr. Hudson for reporting in the *British Medical Journal* of April 12th (p. 693) a case of death during spinocain anaesthesia will be still greater if he will kindly supplement the statement with a few further details.

How many cubic centimetres of spinocain were injected in this case, and how much, if any, cerebro-spinal fluid was mixed with this in the syringe? Will he tell us how soon after the injection, and to what angle, the head end of the table was lowered? Was the patient's condition, prior to the operation, one that inevitably carried a high risk with it—for example, had he carditis or intestinal obstruction? What was the upper level of cutaneous anaesthesia achieved? At what level of the vertebral column does he usually inject for abdominal operations?

I hope he will forgive me for troubling him for these details, but I feel that they are important, as spinocain is a new anaesthetic still on trial in many hands.—I am, etc.,

A. WILFRID ADAMS, M.S., F.R.C.S.

Clifton, Bristol, April 13th.

BED FOR DENTAL EXTRACTIONS.

SIR,—Sir William Willcox, in the address on dental sepsis, of which you gave an abstract in your issue of March 29th (p. 605), lays stress upon the importance in certain cases of the patient being kept in bed continuously until all the septic teeth have been extracted. The wisdom of this procedure has undoubtedly been proved by the rarity of any harmful reaction following the extractions in the large number of cases I was privileged

to see with him during the time I served on the staff of St. Mary's Hospital. Unfortunately, however, there are a very large number of patients who come "on their own," or are referred to us by their medical advisers, who neither know nor have been told of the importance, at least as a precautionary measure, of following this practice. It is clear that the onus is on the medical adviser; for if the suggestion comes from a dentist it is often not accepted, nor is the same weight attached to the opinion of the medical practitioner if it be given after the consultation with the dentist as when it is given independently. This is, I have found, especially true in cardiac cases, the gravity of which patients do not seem to realize, nor indeed did I until I had bought experience. I have previously urged this matter elsewhere, but not in medical journals. I have had many opportunities of noticing the astonishing difference between the manner in which a patient in ill health reacts even to such a "safe" anaesthetic as nitrous oxide if given to him at home in bed and when he has come to me.—I am, etc.,

London, W., April 5th. W. H. DOLAMORE.

QUININE IN ALBUMINURIA.

SIR,—Are there any contraindications to the use of quinine in pregnancy? If so, is albuminuria one? An indirect answer may be afforded by the following history of a man whom I advised, before I had discovered that his urine was heavily loaded with albumin, to take quinine, and whose renal condition under this regime seemed to clear up completely.

A mine surveyor, aged 28, married, with two children, presented himself six years ago for insurance examination. He had aortic regurgitation, and admitted to having had three attacks of rheumatic fever, the first when he was 3 years of age. In addition I found splenic enlargement indicating latent malaria. I told him that it was doubtful if he would be accepted, except on a heavy premium, and in view of his splenic enlargement I advised him to take five grains of quinine daily. When I got home I examined his urine and found that it was heavily loaded with albumin. Accordingly I wrote advising him that it was useless to proceed with his proposal.

Three months later, passing through his district, I thought I recognized him at a distance, but his appearance was quite different, not till he spoke to me was I sure of his identity. He had the appearance of a perfectly healthy man, and had put on over a stone in weight. Needless to say, I was astonished, and asked if I might again examine his urine. It was entirely free from albumin.

I followed him up for a time; he kept quite well, and then went to a mine in another part of the country. Just over a year ago, travelling through his new district, I was accosted by him joyfully at the station; he said I had saved his life. If I had, I had done so accidentally.

Though in the course of twenty years' experience I have never noted any damage to the kidney as the result of prolonged quininization I don't whether, had I known about this patient's albuminuria, I should have advised him to take quinine. His history and symptoms, together with the albuminuria, had led me to believe that his kidneys had suffered permanent damage. In malaria albuminuria is uncommon, and when it occurs it is transient.

This case, as I have already implied, has only an indirect bearing on the administration of quinine to patients with albuminuria of pregnancy, but it suggests that where the renal disorder is not permanent, or is brought on by some combination of causes, one or more of which may be temporary, quinine is not necessarily contraindicated. Cautious and deliberately prolonged treatment may justifiably be undertaken, the intramuscular route being preferable at the beginning.—I am, etc.,

N. Rhodesia, March 15th. W. M. HEWETSON.

DOSE OF MERCUROCHROME BY THE MOUTH.

SIR,—May I ask if medical men who have had actual experience of giving mercurochrome by the mouth would be good enough to communicate their results, and mention the dose they have employed? There have been statements in the American literature recently to the effect that 300 mg. (5 grains approx.) have been given thrice daily, and in consequence chemists are receiving prescriptions for doses which create misgivings. It seems possible that some of the organically combined mercury in the compound may be converted into an ionized or inorganic form, on passing through the system, and hence prove dangerous—either promptly or by cumulative effect. It has been stated further that the chemical is administered in keratin-coated capsules. May I mention that keratin, as commonly employed, is useless as an "intestinal coating," and it would be helpful if medical men with experience of its administration would say definitely whether it is important that mercurochrome should be dispensed in such a manner as to withstand the acidity of the stomach.—I am, etc.,

London, W., April 5th. W. H. MARTINDALE.

Obituary.

JOHN MACKIE WHYTE, M.D.,

Consulting Physician, Dundee Royal Infirmary.

WE regret to announce the death, on April 10th, of Dr. J. Mackie Whyte of Dundee. He had been in failing health for some time, and retired from active practice five years ago.

John Mackie Whyte was born in 1853, and received his medical education at Edinburgh, where he graduated M.B., C.M. in 1882; in the following year he obtained the diploma M.R.C.S.Eng., and in 1897 he proceeded M.D. with honours. After further studies at Göttingen and Vienna, and a year as demonstrator in anatomy in the University of Edinburgh, he began his long association with Dundee in 1884 as resident in the Royal Infirmary there. A year later he took up private practice in that city, and became in turn pathologist, visiting physician for 29 years, and subsequently consulting physician, to the Royal Infirmary. On the establishment of a medical school at Dundee he was appointed lecturer in clinical medicine at University College, and he continued to teach there for some twenty years. He also lectured on clinical medicine in the University of St. Andrews, and was an examiner in medicine to the University of Edinburgh. He published a number of valuable studies, the most elaborate being his report in *Brain*, in 1898, on four cases of Friedreich's ataxia, in which he reviewed fully the available literature.

Dr. Whyte was an active member of the British Medical Association, and held office as president of the Dundee Branch in 1905. He was also for a time president of the Forfarshire Medical Association. He was a keen supporter of the volunteer movement, and for many years was medical officer to the 1st Volunteer Battalion of the Black Watch. During the war he held a commission in the R.A.M.C., serving in Aberdeen and the Dundee War Hospital; he was later placed in charge of the medical side of the 58th General Hospital in France, with the rank of major. He was a justice of the peace for Dundee. Dr. Whyte, whose daughter, Mrs. Cameron, is a member of the medical profession, leaves behind him a high reputation for sound clinical judgement and devoted loyalty to the interests and traditions of his profession.

HERBERT JAMES HOTT, M.D.,

Late Senior Warden of the Apothecaries' Society, and Chairman of the Bromley Division, British Medical Association.

WE regret to record the death, on April 3rd at Midhurst, of Dr. H. J. Hott, for many years senior partner in the oldest medical firm at Bromley, Kent. He was the third of four Hotts who, in unbroken descent, have practised in that town during the past 125 years and taken a leading part in the public and social life of the district.

Herbert James Hott was born on September 10th, 1852, at the old house in High Street, Bromley, where his father was in practice, and, following the family tradition, he decided to become a doctor. Entering as a student at St. Bartholomew's Hospital in 1869 he was awarded a senior scholarship in medicine, surgery, and midwifery, and in 1873 won the Kirkes gold medal for clinical medicine. He then went for a year with some of his fellow students to Aberdeen, graduating M.B., C.M. at the university with highest honours in 1874, and obtaining the M.R.C.S.Eng. and L.S.A. diplomas. He proceeded

M.D.Aberd. in 1878. Meanwhile, after holding resident appointments, he had joined the family practice and was at once appointed medical officer to the Bromley Cottage Hospital, afterwards becoming surgeon to the Police and the Post Office. In 1909 his son Dr. Cyril Ilott joined the firm, and he himself retired in 1926 after fifty years of general practice, during which time Bromley grew from a small country town into an important suburban borough. From beginning to end of his active professional life Dr. Herbert Ilott was assiduous in keeping abreast of new work in clinical medicine, surgery, and obstetrics. He read the medical journals every week and always had some new monograph or textbook in hand. Yet with this and the claims of a large practice he found time to associate himself with educational, religious, and benevolent organizations, and to help in many other good causes. In youth he had been an ardent entomologist, and throughout his life was devoted to fly-fishing. He was an old liveryman of the Apothecaries' Society of London, serving in recent years as Junior Warden and Senior Warden, but declining on grounds of health to be nominated for the office of Master. He took little part in medical politics, though he followed the course of events, and his local colleagues found him a trusted counsellor in professional difficulties. In 1923–24 he was chairman of the Bromley Division of the British Medical Association, of which he had been a member since its formation. Herbert Ilott was a wise and skilled practitioner: an all-round doctor of the best type, devoted to his work and to his patients; an upright English gentleman and the kindliest of friends.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

British Post-Graduate Hospital and Medical School

IN the House of Commons, on April 9th, Mr. CHAMBERLAIN asked the Minister of Health whether he was in a position to state what action the Government proposed to take on the report of the Post-Graduate Medical Education Committee.

In his reply, briefly reported in the *British Medical Journal* of April 12th (p. 709), Mr. GREENWOOD said:

In view of the public interest in this matter I hope that the House will permit me to make a statement which exceeds the usual limits of a reply to a question. The committee was appointed by my predecessor. He was, as Minister of Health, its chairman, and I succeeded him. The report will be in the hands of members to-day. The proposal of the committee is *that, in order to remedy the most serious outstanding defect* in the existing provision for the education in medicine of post-graduate students, a British Post-Graduate Hospital and Medical School should be established in London. The organization of the British Post-Graduate Hospital and Medical School recommended by the committee consists of an existing public hospital, the Hammersmith Hospital, with 400 beds in modern wards, which on April 1st became the property of the London County Council under the Local Government Act, 1929, a medical school in conjunction with the hospital, and a residential hostel on a site in Central London. The committee estimates that the financial provision required to establish and maintain the British Post-Graduate Hospital and Medical School, apart from the cost of the maintenance of the beds in the public hospital—which in its view should remain, as it *is now, a charge on* the ratepayer—will be as follows. First, a capital sum not exceeding £250,000 for building a medical school, which, together with the hospital, will form the main part of the new organization and for providing educational equipment. *Secondly, the sum necessary to maintain the* medical school as a recognized school of the University of London. Thirdly, the capital cost of building the residential hostel. The Government has accepted the recommendations of the committee as to the organization of the British Post-Graduate Hospital and Medical School. It is much impressed with the importance of securing without avoidable delay the advantages of a proper system of post-graduate medical education in London, not only from the domestic but also from the imperial and from the international point of view. The Government will accordingly be prepared to contribute from public funds a maximum sum of £250,000 for building and equipping the medical school as an integral part of the scheme recommended by the committee, and to make provision for grants through the University of London towards the maintenance of the school on the lines already applied to comparable institutions of university rank. The Government earnestly hopes that it may secure the co-operation of the London County Council and of the University of London in the scheme as recommended by the committee, and it is entering into communication with those bodies on the subject. The Government understands that an appeal will shortly be made to the public for assistance in the establishment in London of a residential institution, to be called "London House," for the use of students from the Dominions, not only in medicine but in other arts and sciences. It is also part of the proposed scheme that "London House" shall offer accommodation to a limited number of British students domiciled in Great Britain and Northern Ireland in order to furnish collegiate association between them and students from the Dominions. Such an institution would, in fact, secure the object aimed at by the Post-Graduate Medical Education Committee in recommending the provision of a hostel. The Government is in full sympathy with the movement, and it looks forward with full confidence to the success of the appeal when it is made as crowning a scheme to which the taxpayer, the ratepayer, and the general public will be contributing their appropriate shares.

Mr. CHAMBERLAIN: I am sure that the statement which the right hon. gentleman has just made will give profound satisfaction as soon as its full implications are appreciated. In congratulating him upon the final success—which I am sure he will agree is largely due to the very distinguished body of surgeons and physicians constituting the committee—may I ask him whether the hospital which has been chosen is considered to *have a sufficient* number of beds for the purpose for which it is required, and whether, if not, there is room for extension in future, if it is considered desirable?

Mr. GREENWOOD: Yes, Sir. The scheme envisaged by the committee makes provision for a larger number of beds than is now available at Hammersmith. The committee was unanimous in its choice of Hammersmith, and there is sufficient available ground for extension and the number of beds to make the hospital effective.

Mr. MARLEY asked whether it was proposed that colonial students, as well as students from the Dominions, would be able to reside at "London House," as there were post-graduate students from Africa taking courses in tropical medicine.

Mr. GREENWOOD: If I used the term "Dominions" narrowly I am sorry. The hostel will be available for students from all parts of the British Commonwealth. In answer to Miss Rathbone, Mr. Greenwood said that men and women would both be included in the scheme.

Mental Treatment Bill

REPORT STAGE.

The House of Commons considered, on April 11th, the Mental Treatment Bill as reported with amendments from a Standing Committee. On Clause 1, power to receive voluntary patients, Dr. VERNON DAVIES moved to omit "*for mental illness*" in the opening phrase of the bill, which runs: "Any person who is desirous of voluntarily submitting himself to treatment for mental illness."

Colonel WEDGWOOD intervened to ask why he had not been permitted to move the omission of the clause in order to debate whether the persons to whom it was related were really voluntary boarders or whether they were compelled to become boarders by the fear of being certified.

Mr. HOLFORD KNIGHT remarked that the clause created an entirely new category of persons, and suggested that the House should first debate whether that category should be created.

The SPEAKER said he could not depart from his action in calling upon Dr. Davies. The House had taken a decision on the general principle during the second reading. There were plenty of amendments on which the question raised by Colonel Wedgwood could be debated.

Dr. DAVIES then proceeded to move his amendment. He said the bill was not a Lunacy Bill, but was intended to get patients in the earlier stage of mental illness to submit themselves to treatment. There was in the mind of the general public a horror and shame at the name "lunacy." The further the House could keep away from any association with lunacy the more successful the bill would be. For the first time Parliament was attempting to deal with mental illness in the same way that it dealt with physical illness. Mental disorder or mental illness consisted of a variety of different diseases, and it was quite unnecessary to say that a name must be given to it in the bill. The Lunacy Act, which dealt with patients who were certified, never mentioned mental illness or lunacy. Under the first clause of the present bill any person who desired voluntarily to submit himself to treatment had to make written application to that effect. Nowhere was any form laid down in which that application was to be worded.

A patient might say, "I, feeling that I am worried, nervous, anxious, and cannot sleep, wish to apply for treatment." That would cover the ground sufficiently and take away from the patient the idea of mental trouble. But if a man in signing an application form had to say "I desire to submit myself to voluntary treatment for mental illness," he might think, "I will not run the risk," and his family would try to prevent him.

Mr. CHARLES WILLIAMS seconded the amendment.

Mr. GREENWOOD (Minister of Health) said Clause 1 did not invent a new category of patient. Voluntary patients had been known to the Lunacy Act for half a century. Under the Act of 1890 they were received into private institutions. The only object of the clause was to enable such persons to be treated in mental hospitals and not approved places. It was necessary to define what kind of treatment was contemplated, and there was nothing derogatory in describing in a Bill the plain facts about a person's illness. Nothing could be less objectionable and more neutral than the term "mental illness." Unless those words were kept in, the clause would not convey its object. There was a difference of medical opinion on this point.

Captain CROOKSHANK pointed out that during the discussion in committee, Dr. Fremantle had intimated that the Royal Medico-Psychological Association considered that if the words were inserted in the Bill this would keep out certain patients who otherwise might receive treatment. It was left to the Minister to decide who it was best able to give them. It appeared that a division was going to be taken, especially as the Government alone failed.

Dr. VERNON DAVIES urged that voluntary treatment when physical treatment was required should be given in a mental hospital. The amendment was negatived without a division.

Mr. KINLEY then moved to substitute the Minister of Health for the Board of Control as the authority to approve hospitals, nursing homes or other places or persons for the purposes of Clause 1. The question of control was of fundamental importance. Mr. Kinley said the amendment was of fundamental importance. Mr. Kinley said the amendment was of fundamental importance. Mr. Kinley said the Home Secretary upon his proposal would decide whether the bill would the House upon his proposal would decide whether the bill would be of value to the public. The Board of Control should have nothing whatever to do with this new service from beginning to end. During the Board was allowed to come in that service would be doomed to failure. The who had drafted the bill were ignorant of the attitude of general public towards mental institutions as they at present exist and towards those who control them. The public learned to dread the very name of asylum and of all with it. The Board had only itself to blame that while 22,000 persons on the average had left asylums in England and Wales during several thousand suicides must be added to like 30,000 ally relapsed they should by the same conditions as passage of the bill to prevent within the change of people that the control had decided that the worthy of altered. The until it first of all vested in it had ascertained that asylums every twelve months. He was tions had been made into the ing to the Ministry of Health mental institutions that arrangement should be made That was entitled to have the Parliament entitled to have the highest direct or indirect contact with the new mental service and the bill.

Mr. MESSER WOOD said there was not a word in the report of the Royal Commission to substantiate the reckless statements which had just been made. Mr. Kinley ought not to take advantage of his privileged position as a member of Parliament to make charges which were not made before the Royal Commission. It was unfair to men who endeavoured to do their work with sympathy and efficiency. To place voluntary boarders under the Ministry of Health would duplicate machinery and set up two administrative staffs. Voluntary boarders were under the jurisdiction of the Board now, and there had been no complaints concerning their treatment. He contended that the House could not accept the amendment, but he hoped the Minister would retain the lay element on the Board of Control to inspire greater public confidence in its operations.

Colonel WEDGWOOD said the House must reserve liberty to attack public departments. The proposal at issue was not merely to take out the words "Board of Control" and substitute "Ministry of Health," but to decide whether voluntary boarders should go to a lunatic asylum or to other institutions free from the taint of connexion with lunacy. It was true there were not at present enough of these institutions, but if the Ministry of Health was in charge of the matter institutions would be built sooner or later by the local authorities to deal with this particular class of case. Till there were such institutions, free from the lunacy taint, the people would volunteer for treatment under Clause 1. The fear of being sent to a lunatic asylum was the dread of people on the borderland. They feared perpetual incarceration, where they always had to obey orders, where their complaints did not count, and where there was no hope of getting out except by the decision of some expert. When authorities were dealing with poor people there was a very thin line between what was voluntary and what was coercive. The House was adopting a proposal which it knew to be wrong simply because members' brains were deadened by doctors and experts, who knew much better what was good for people than people knew for themselves. There ought not to be the possibility of any British citizen, if not quite insane, being locked up without being able to state his case to a court of law, and without having some appeal against the decision of two doctors.

Dr. MORRIS-JONES said the Board of Control dealt with thousands of people not one of whom was mentally normal, and it had done its work extraordinarily well. It was unfortunate that in 1913 the Board had been given its present name, because British people did not like the word "control." Sir Maurice Craig, who at one time had been much against the Board of Control, was now of opinion that it was fitted to undertake the supervision of all mental patients, including those in the early stages of illness. The final conclusion of the Royal Commission in 1926 was that the Board had discharged its duties in a manner deserving of great commendation, but had been handicapped by factors beyond its control. The present bill was to remedy those handicaps. Dr. Morris-Jones said he was amazed at the way the Board was constantly assailed on all sides. He had great hopes in the present clause. Medical men would make great use of it and would encourage patients to take voluntary treatment and so avoid serious mental disorder later on. Every successful doctor was an optimist. Gloomy doctors, as a rule, went their rounds on foot.

Mr. GREENWOOD said the clause under discussion did not represent the views of bureaucrats or experts, but the conclusions of a Royal Commission, which was neither expert nor bureaucratic in composition. The voluntary boarder had existed under the law for a considerable time. Nearly one-half of the entrants to registered houses and hospitals were people who went up voluntarily. It might appear surprising that any person should go to a mental hospital voluntarily, but times had changed, and statistics showed that they did so. During 1929 there were admitted to registered hospitals 569 certified patients and 662 voluntary patients. Into licensed houses 974 certified patients were admitted and 757 voluntary boarders. The amendment did not ask the House to abolish the Board of Control or to supersede it by the Ministry of Health. That would require a bill amending drastically the principal Act of 1890. The amendment asked that the Ministry of Health should be directly responsible for certain aspects of mental illness while retaining the Board of Control for the major portion of responsibility for mental health. That would mean that in most cases the medical visitor of the Board of Control and the medical visitors of the Ministry of Health would go into the same institutions. Moreover, a man might to-day be a voluntary patient and next week incapable of volition. He might then fall within the category of persons certified as of unsound mind. What were they to do about people who oscillated between one category and another? It was perfectly open for a local authority to organize the institution under its control so as to provide specially for voluntary patients. It was inaccurate to assume that there was nothing for the voluntary patient except the mental hospital, though in a numerous of cases at present it was either that or nothing. On the whole he would rather have the mental hospital than nothing. Finally, he would say that, whether the supervision remained under the Board of Control or whether Parliament decided that it should come under the Minister of Health, the Ministry would be equally responsible. On practical grounds the House ought not to accept Mr. Kinley's amendment.

Mr. WOMERSLEY asked whether the Minister would accept an amendment giving local authorities a right of appeal to the Ministry of Health against any direction by the Board of Control.

Mr. GREENWOOD replied that on that matter he stood where he did during the committee stage.

Mr. MCSHANE said that when there was any complaint against the Board of Control it was impossible for members to get a grip upon it. If this bill passed, the House would have less control of the Board, whereas he, as a socialist, wished to have a closer control of every department.

Mr. BECKETT said that during his six years as a member of Parliament he had taken up many cases with the Board, and he could not remember a single one in which he felt satisfied that the Board had done the right thing, or in which its correspondence had been fair, honest, and candid. He cited a case of what he alleged to be erroneous certification in Gateshead, and said that in this case he had been able to trace the lies, the malevolence, and the libellous statements of the Board of Control. He had been able to take the case to the Minister, and by threats of publicity to get an apology. Whenever people got into the charge of the Board it sought to detain them by every excuse. The Board was permeated by the worst type of charity organization mentality.

Dr. VERNON DAVIES hoped that Mr. Beckett had given the Minister of Health warning before making a deliberate charge against the Board of Control and instancing a specific case.

Mr. BECKETT said the case had occurred in 1929. He had taken it up with Sir Kingsley Wood, who had made representations to the Board.

Dr. VERNON DAVIES said the Board could not answer for itself, and the Minister should have been informed so that the charge made could have been met on the floor of the House. Dr. Davies went on to say that he could not agree with Mr. Kinley's amendment. The bill as it stood was lowering the Board of Control by making it a department of the Ministry of Health. Some members had a wrong idea of the functions of that Board. It could almost be described as a judicial body. It acted as judge on all documents or medical certificates, and was the guardian of the liberty of the subject. When members of the Board went round mental hospitals and other places they did not certify, but simply examined cases. They saw that patients got out as quickly as possible, and that no one was being detained unnecessarily. To reduce the Board in status as it was being reduced under this bill by placing it under the Minister of Health was to weaken its position. There was no more difficult department of State with which to deal than the Ministry of Health. At the present time the Board of Control, being appointed by the King, was in a superior position, separate and distinct from the Civil Service, and in the interests of the people of the country it should be kept in that position.

The House then divided on Mr. Kinley's amendment, which was rejected by 205 to 18.

Mr. ERNEST WINTERTON moved to add at the end of the subsection dealing with reception of voluntary patients the words:

"But unless the said voluntary patient is of unsound mind within the meaning of the Lunacy Acts, 1890 to 1922, he shall not be received or lodged as a patient, either rate-aided or paying, in a public mental hospital (asylum)."

Mr. FENNER BROCKWAY seconded the amendment. He said that within an institution it was impossible to guarantee that there would be no communication and no contact between various classes of patient. He knew there were laws in these institutions about segregation, but association would take place, and the effect was bound to be bad in borderline cases. His friends wished to see a positive and constructive medical health service developed under public authority and under the control of the Ministry of Health.

Miss LAWRENCE said the persons to whom the clause referred could not be taken against their will into a lunatic asylum. They had to apply to the person in charge of a particular institution to be received into that institution. These people were sane; they were not certified, and no one could send them anywhere. They would go to institutions which dealt with all classes of cases between lunacy and the mildest forms of mental worry. The doctor best qualified to look after the very mild cases was a man with experience in the advanced stages of the disease. Anyone who attempted to draw a line between melancholia and the depression which might lead to melancholia was still under the old absurd delusion that lunacy was an affliction from the devil. People had been going into general institutions for voluntary treatment. They now flocked to Edinburgh and to the private institutions, and to the private practitioners who were allowed to take people into their houses.

Dr. VERNON DAVIES said the number of voluntary patients had increased lately because relatives had been afraid of certification, and because medical men had refused to certify on account of the financial and legal difficulties which might ensue. He himself sympathized with the amendment. The worst thing which could happen in an early case would be for the patient to find himself in an asylum. Parliament must exert pressure on local authorities to supply voluntary general hospitals which were not mental hospitals. Under the new Local Government Act a borough or county authority could establish convalescent homes for these early cases with no asylum environment. At present there was no place for many of those who were anxious to receive the benefit of the measure.

Dr. FREMANTLE supported Dr. Davies. He said they could not draw a hard-and-fast line between curable and incurable mental disease. They might as well try to institute separate institutions for curable and incurable heart disease. Nature was so recuperative that they could not say that a case which was supposed to be incurable would not show a sudden and unexpected improvement. Medical men looked forward to a time when local authorities would have institutions in which people seeking rest might go for treatment, and ultimately to a time when mental sickness would be treated as part of general sickness. The number of experts on the staffs of mental hospitals was limited. The authorities could not suddenly devise new institutions, because there were not experts to run them. To have a new set of institutions all over the country would not be practicable within twenty or thirty years. The amendment would refuse help to people who required seclusion and quiet by forbidding them to go into county asylums, however well and kindly they might be managed. He knew that in his own county of Hertfordshire the mental institution had the confidence of the great mass of people, and that many would be delighted to avail themselves of it.

The amendment was then negatived.

Colonel WEDGWOOD moved to omit from Clause 1 subsection 2, which deals with the reception as a voluntary patient of a young person under the age of 16, on the written application of the parent or guardian, accompanied by a medical recommendation. Colonel Wedgwood said this established a dangerous principle. In cases where money was involved in the guardianship a judicial investigation was desirable before a young person was taken into an institution. In a borderline case, like that of a sexually precocious child, how was the Board of Control to know better than the doctor or the parents whether that child should be locked up?

Mr. GREENWOOD said the bill provided the best conceivable kind of protection.

The amendment was withdrawn, and the committee passed to Clause 2, which deals with the notice of reception, death, or departure of voluntary patients, and with provisions as to the discharge of patients.

Colonel WEDGWOOD moved to amend the subsection dealing with the decision on the incapacity of a patient to express himself as willing or unwilling to continue to receive treatment. His amendment provided that after the word "incapable" there should be inserted "in the opinion of a magistrate." He said it was the business of the judiciary to be responsible for incarceration, and not the business of doctors. A magistrate's certificate took some of the responsibility off the doctors, who were only responsible for the state of the person's health. That a magistrate could be seen, and could possibly support the patient against the doctor, was something of a safeguard, and should be preserved in the law. The bill would leave in the hands of the doctor, or of the superintendent in charge of the institution, a vital power to decide whether a temporary boarder was to become more or less a permanent inmate of the place. He could be transferred from Clause 1 to Clause 5 without a decision by anyone except the superintendent. The question whether a person was capable of "expressing himself willing or unwilling" was one which a magistrate could decide much more easily than he could decide many cases of certification.

Mr. GREENWOOD said there was a clash of principle on this amendment. He favoured the exclusion of magisterial interference to the largest possible extent. The Royal Commission had reached the same opinion after full consideration. Mental disease was in no wise different from physical disease except in the question of personal liberty. Even there the difference was more apparent than real. In a case of highly infectious disease where was the liberty of the subject? If Parliament could get rid of judicial interference, and get away from the stigma of certification, they would help these unfortunate people. The Royal Commission had also desired to get away from the use of any judicial authority, but elaborated a procedure which could not have been distinguished from certification, and therefore the Government had cut it out.

Dr. MORRIS-JONES said the intervention of a magistrate in these cases was harmful. He spoke not only as a medical man, but as a magistrate. In Scotland for over seventy years there had been no magisterial intervention in these cases; neither was there any in Ireland. He suggested that Parliament should follow these examples.

Colonel WEDGWOOD said he understood that the Royal Commission had urged that the appeal to the judiciary should be strengthened, and that the magistrate was not good enough. In the clause Parliament was taking away from the magistracy an opportunity in which it could be far more useful than in certification.

The amendment was then defeated by 192 to 30, and, the debate having lasted practically the whole of the parliamentary day, Mr. GREENWOOD moved its adjournment, to which the House agreed.

The Government had proposed to secure the reports of the twenty-three clauses in the bill and four schedules, and also the third reading of the bill on April 11th. Actually discussion was only carried to a point midway in Clause 2. It is understood that the Government, although disappointed at the development of obstruction to the bill from its own side of the House, is still confident of securing the passage of the bill, and will assign time for the purpose after Easter.

MEDICAL NOTES IN PARLIAMENT.

Medical Officers of the Chief Medical Officer of the Board of Education

Replying to Dr. Vernon Davies on April 6th, Sir C. Trevelyan said that it was a practice of long standing for the Board of Education to recommend for the Board's medical staff persons who had been approved by the Civil Service Commissioners as the result of competitive examinations. The practice was followed in the case of the Board's medical officers, and he was aware of the fact that certain doctors of various qualifications had been appointed by the Civil Service Commissioners. He would call their attention to the matter.

Radium Treatment at Hull

Sir Lancelot Spratt, on April 10th, asked the Lord Privy Seal whether the Government, in view of the fact that the Hull Corporation had decided to provide radium treatment for the people of Hull, would consider the question of making a grant to the Hull Royal Infirmary for the purpose of providing radium treatment for the people of Hull.

Mr. W. W. Fraser, medical officer of health for Hull, said that the Hull Royal Infirmary had expressed a desire to purchase a radium unit. The Hull Royal Infirmary had agreed to be responsible for the radium. As a result they would have to pay a grant of £5,000 for the purchase of radium for the Hull Royal Infirmary, which would be administered by the Hull Royal Infirmary.

Mr. Morrison, Minister of Health, said he did not think that the special circumstances that required this special treatment was desired to extend.

Dr. Haden said the question was thinking of those people who did not have the means to pay. It was also proposed to make a nominal charge. The matter fully with the Ministry of Health.

Mr. Morrison said that a question of Landing out radium.

admitted that the words of to mean that, but it would be to a way to satisfy the instances, insert a Provision to with special qualifica-

nths a medical officer of the

his clause in the bill. Hull radium centre under to to expect people to go for

Mr. Paling said that in the clause seems to make some provision for this treatment would be available the hands of the Royal Infirmary acted with the Royal Infirmary. The clause was

Accommodation for Mental Patients.

Answering Mr. Kimber on April 3rd, Mr. Greenwood said there were in England and Wales forty-four local authorities under the Lunacy Act, 1890, and one under local Act, which had accommodation in excess of that required for patients who belonged to their own area, and the total number of beds in excess was 5,242. Most of this surplus accommodation, however, was occupied by patients received under reception contracts from other local authorities who had insufficient accommodation or did not own a mental hospital. Private institutions under the Lunacy Act had sufficient vacant beds to meet normal requirements. In the case of mental deficiency institutions there was no accommodation in excess of normal requirements.

Mr. Kimber further asked the Minister of Health the average number of patients in institutions under the Lunacy Act jurisdiction of the Board of Control.

Mr. Greenwood replied that in institutions under the Lunacy Act the average number of patients to each member of the resident medical staff was (a) in county and borough mental hospitals, 290; (b) in registered hospitals, 61; and (c) in licensed houses, 25. Most of these institutions had, in addition to their resident staff, a number of visiting consultants. In mental deficiency institutions the average number of patients to each member of the staff, resident and non-resident, was 111.

Mr. Greenwood also told Mr. Kirby that in 1929 the number of patients who died in institutions for the insane under the Lunacy Acts was 9,775, compared with 8,747 in 1928 and 9,292 in 1927. In institutions for mental defectives 220 died in 1928, compared with 222 in 1928 and 209 in 1927. These latter figures did not include deaths in Poor Law institutions approved under the Mental Deficiency Act, 1913.

In answer to Mr. Sorensen, Mr. Greenwood stated, on April 3rd, that in England and Wales there were 16 institutions registered under the Mental Deficiency Acts, but were in widely different stages of development. There were at present 16,592 patients. The cost of colonies for mental defectives was under consideration by a committee, whose advice must have a bearing on the provision of further accommodation.

Indian Medical Degrees

On April 13th, Mr. Bann in reply to Mr. Freeman, said that he had nothing to add to his reply of March 20th with regard to the action of the General Medical Council in withdrawing recognition of Indian medical degrees in India. Mr. Freeman asked if Mr. Bann was aware of the widespread indignation which the matter had aroused, and if anything could be done to expedite its consideration. Mr. Bann replied that he was certain the Government of India was fully aware of the importance of the matter, and was dealing with it as expeditiously as it possibly could. Mr. Freeman asked if it was in the power of India to withdraw similar recognition of English medical degrees in India. Mr. Bann asked for notice of the question.

Cutaneous Disinfection of Hides and Skins

In reply to Dr. Salter on April 2nd, Mr. Shakespeare said a full account of the results of the British Leather Manufacturers Research Association on the disinfection of hides and skins from anthrax would probably be published in a scientific journal, though some account was given in the monthly publication of Annual Report of the Ministry of Health for 1928-29. He was considering whether some advance statement should be issued.

Health Organization of the League of Nations

Miss Lawrence, on April 5th, told Mr. Foot that the Health Organization of the League of Nations included the Health Committee, of which a medical officer of the Ministry of Health was a member, and the Health Section of the Secretariat. The latter included British nationals, but they were not appointed as representatives of this country.

Royal Army Medical College

Mr. Shaw, replying on April 1st to Dr. Vernon Davies, said that the maximum number of students who could be trained at one time at the Royal Army Medical College was 62 officers and 24 other ranks. The estimated cost of the College including the vaccine department, as shown in the Army Estimates, was £33,590 in 1927, £36,890 in 1922, and £37,223 in 1923. The vaccine department was working to its full normal capacity.

Causes of Rejection of Recruits for the Army

Mr. Shaw, replying to Mr. Hastings, said that the main physical defects which caused the rejection of recruits for the Army by the examining medical officers were diseases of the middle ear, defects of many teeth, defects of lower extremities, defective vision, disease of the heart, insufficient weight, flat feet, and pulmonary defects. Information was not available to show the physical defects for which recruits were rejected by recruiting authorities other than medical officers.

Expenditure incurred by the Scottish Health Department

Mr. Lennox on March 28th, told Mr. J. Welsh that the estimated net expenditure to be incurred by or on behalf of the Department of Health for Scotland during the year ending March 31st, 1930, was £3,160,000. The combined expenditure incurred by the Government Board for Scotland, the National Health Insurance Commission (Scotland), and the Highland and Islands Medical Service Board in the year 1913-14 was £674,000. The estimated expenditure of the Department on housing during 1929-30 was £1,652,000.

Grants for Medical Research

On April 3rd Mr. Perkins told Dr. Forgan that the annual grant-in-aid of the Medical Research Council was £149,000. He had no reason to think that was inadequate. It was by no means the only contribution made by the State to medical research.

Notes in Brief

Mr. Shaw states that the only laboratory other than that of the experimental station, Porton, where experiments on living animals are conducted in connexion with chemical warfare is the physiological laboratory, Cambridge.

Imports of milk from outside the British Isles are subject to examination for tubercle bacilli under the Imported Milk Regulations. There is no examination of imported cream for this purpose.

Mr. Shaw told Dr. Salter, on April 2nd, that the number of persons killed on the highways during 1923 by mechanically propelled vehicles was 5,339 in England and Wales, and in Great Britain 6,016.

Universities and Colleges.

UNIVERSITY OF LONDON.

THE latest date for the receipt of applications for the Chair of Bacteriology at University College Hospital Medical School (salary £1,200) is May 15th.

Dr. A. F. MacCallan has been recognized as a teacher of ophthalmology at Westminster Hospital Medical School, and Mr. S. G. Scott as a teacher of radiology at the London Hospital Medical College.

Dr. H. D. Wright has tendered his resignation as Reader in Bacteriology at University College Hospital Medical School as from August 31st, in view of his appointment to the Chair of Bacteriology in the University of Sydney.

The Prime Minister will be the principal guest at the graduation dinner to be held on Presentation Day, May 14th, at the Fishmongers' Hall, and the annual service for members of the University will be held at Westminster Abbey on that day at 5.30 p.m.

Mr. F. S. Read, B.A., has been appointed Warden of the University Union as from April 1st.

Lecture Programme.

Two lectures on some biological aspects of the human skin will be given at St. Thomas's Hospital Medical School by Dr. H. Leslie-Roberts on May 1st and 2nd, at 5.30 p.m. Dr. S. E. Dore will preside at the first lecture.

A course of six lectures on the early history of generation and comparative anatomy will be given by Professor F. J. Cole, F.R.S., at University College, Gower Street, W.C.1, on May 7th, 8th, 14th, 15th, 21st, and 22nd, at 5.30 p.m. Professor G. Elliot Smith will take the chair at the first lecture.

Professor J. A. Gunn will give three lectures on pharmacological reactions of involuntary muscle at King's College, Strand, W.C., on May 7th, 8th, and 9th, at 5 p.m. The chair at the first lecture will be taken by Dr. Philip Hamill.

The treatment of uterine cancer by radiations is the subject of a course of three lectures to be given at the London (R.F.H.) School of Medicine for Women, Hunter Street, W.C.1, on May 12th, 13th, and 15th, at 5.30 p.m., by Dr. A. Lacassagne of the Pasteur Laboratory, at the Institute of Radium, Paris. Professor Dame Louise McIlroy, D.B.E., will preside at the first lecture.

Six lectures on special sense physiology will be delivered by Dr. R. J. Lythgoe at University College, Gower Street, W.C.1, on May 15th, 20th, 22nd, 27th, 29th, and June 3rd, at 5 p.m.

Admission to the lectures, which are addressed to students of the University and others interested in the subjects, is free, without ticket.

UNIVERSITY COLLEGE.

Bayliss-Starling Memorial Scholarship.

This scholarship has been founded by old students, friends, and admirers in commemoration of Professor Sir William Maddock Bayliss and Professor Ernest Henry Starling. The annual value of the scholarship is about £120, with exemption from tuition fees, and it is tenable at University College, London. The scholar will be required to follow a course of study approved by the Jodrell Professor of Physiology, involving a training in the principles of and methods of research in physiology and biochemistry. Candidates must send their applications to the Secretary of University College not later than Wednesday, May 14th.

LONDON HOSPITAL MEDICAL COLLEGE.

Open entrance scholarships, of the value of £100 each, have been awarded to H. J. Barrie and H. B. Tipler.

UNIVERSITY OF BIRMINGHAM.

THE Clinical Board of the Faculty of Medicine has arranged a course of post-graduate demonstrations on Tuesdays and Fridays, from 3.30 to 5 p.m., commencing at the General Hospital on Tuesday, April 29th, and at the Queen's Hospital on Friday, May 2nd. The course will be given by members of the medical and surgical staffs, and will include demonstrations on medical, surgical, and gynaecological cases. One demonstration, on a Tuesday, will be given at the Children's Hospital, Ladywood Road. The fee for the course is £2 2s. Detailed time tables and tickets of admission can be obtained at each hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting was held on April 10th, when the President, Lord Moynihan, was in the chair.

Fellowship.

The following members of twenty years' standing were elected to the Fellowship: Ernest Edwin Ware, senior surgeon, Hospital of St. *John and St. Elizabeth*; *Frederic Wood Jones, Professor of* Anatomy, Melbourne University.

Diplomas.

Diplomas of Membership were granted to Messrs. A. H. Baker, W. W. Gerrard, C. C. Kapila, J. I. Rerrie.

Diplomas were granted jointly with the Royal College of Physicians in Tropical Medicine and Hygiene to 30 candidates.

Prizes and Appointments.

The Jacksonian Prize for the year 1929 was awarded to Mr. D. H. Patey, F.R.C.S., of the Bland-Sutton Institute of Pathology of the Middlesex Hospital, for his dissertation entitled "The pathology, diagnosis, and surgical treatment of diseases of the salivary glands." A certificate of honourable mention and honorarium was awarded to Mr. Reginald T. Payne, F.R.C.S., chief assistant to the Surgical Unit at St. Bartholomew's Hospital for his dissertation. It was decided that the subject for the Jacksonian Prize for 1931 shall be "The surgery of the sympathetic nervous system."

The John Tomes Prize for 1927–29 was awarded to Mr. Evelyn Sprawson, Member and Licentiate in Dental Surgery of the Royal College of Surgeons of England, for his original work in connexion with the chemical and microscopical structure of enamel and investigations in connexion with dental pathology.

Miss Lilian Eleanor Tracey of the London School of Medicine for Women was appointed Begley Student for the ensuing three years.

The President reported that he had appointed Mr. G. E. Gask as the next Thomas Vicary Lecturer. The President also reported that Dr. Harvey Cushing would deliver the Lister Memorial Lecture on Wednesday, July 9th.

Primary Fellowship Examination in Australia.

A letter of February 27th from Mr. Alan Newton, Honorary Secretary of the College of Surgeons of Australasia, was read, stating that the members of the Council of the College are unanimously in favour of the scheme for holding a Primary Fellowship Examination in Australia, as defined in paragraphs 1 to 15 of the report of the Nomination Committee, dated December 9th, 1929, with the proviso that "Melbourne" be substituted for "Sydney" in paragraph 2; and stating that it is proposed to announce that an examination will, in all probability, be held in Australia in August or September, 1931, if at least 25 candidates present themselves for examination.

Hunterian Lectures.

Six Hunterian lectures on the anatomy of fossil man, illustrated by recent discoveries, will be delivered by Sir Arthur Keith, F.R.S., in the theatre of the College, Lincoln's Inn Fields, W.C., on May 5th, 7th, 9th, 12th, 14th, and 16th, at 5 p.m.

The Services.

DEATHS IN THE SERVICES.

Fleet Surgeon Alfred Thomas Corrie, R.N. (ret.), died at Plymouth on March 28th. He was educated at Bart's, and took the L.S.A. and L.R.C.P.Ed. in 1871, and the M.R.C.S. in 1872. Entering the Navy as surgeon on March 30th, 1872, he became staff surgeon in March, 1884, and fleet surgeon on September 8th, 1892, and retired in August, 1902. He was surgeon of H.M.S. *Pearl* in 1875, at Santa Cruz in the South Pacific, when Commodore Goodenough and two men lost their lives in a treacherous attack by natives, and was in medical charge of the boats sent to punish the outrage. He was the author of a valuable paper on Lord Howe Island, published in the *Transactions* of the Royal Geographical Society.

Colonel David Wilkie, Bengal Medical Service (ret.), died at Coolmore, Falmouth, on February 6th, aged 80. He was born on June 27th, 1849, the son of Mr. David Wilkie of Gorbals, Glasgow, and was educated at the university in that city, where he graduated as M.B. and C.M., with honours, in 1871. Subsequently he studied also at Berlin for a time. He entered the I.M.S. as assistant surgeon on April 1st, 1873, passing first into Netley, was promoted to surgeon three months later, when the rank of assistant surgeon was abolished, attained the rank of colonel on April 2nd, 1904, and retired on April 2nd, 1909. Most of his service was spent in civil employ in the North-West Provinces, now the United Provinces of Agra and Oudh; and during his five years' tour in the administrative ranks was Inspector-General of Civil Hospitals in Assam and Eastern Bengal. He received a Good Service Pension on October 1st, 1908.

Lieut.-Colonel Walter John Weston, D.S.O., R.A.M.C., died at Aldershot, on March 21st, aged 48. He was born on July 3rd, 1881, the youngest son of the late Major A. Weston, 5th Lancers, was educated at St. George's, and took the M.R.C.S. and L.R.C.P.Lond. in 1905. Entering the R.A.M.C. as lieutenant on July 31st, 1905, he attained the rank of lieutenant-colonel on October 13th, 1929. He served throughout the war of 1914–18, was mentioned in dispatches in the *London Gazette* of December 6th, 1916, and July 21st, 1917, and received the D.S.O. on June 4th, 1917.

Lieut.-Colonel Robert Oriel Cusack, R.A.M.C. (ret.), died at Hampstead, on March 11th, aged 75. He was born on February 9th, 1855, and took the M.R.C.S. and L.R.C.P.Lond. in 1877. Entering the Army as surgeon on March 6th, 1880, he became lieutenant-colonel after twenty years' service, and retired on April 16th, 1902. He served in the Manipur campaign on the North-East Frontier of India in 1891, was mentioned in dispatches in the *London Gazette* of August 14th, 1891, and received the frontier medal. He rejoined for service during the war of 1914–18.

Medical News.

IN recognition of his many years' service to the borough, as mayor and in other capacities, Dr. H. B. Brackenbury is to receive the freedom of Hornsey. It will be conferred at a special meeting of the Town Council on May 10th.

THE annual dinner of the Fellows of University College, London, will be held at the College on Wednesday, April 30th, at 7.30 p.m., in commemoration of the laying of the first stone of the college buildings by H.R.H. the Duke of Sussex on April 30th, 1827. Sir John Rose Bradford, President of the Royal College of Physicians, will preside.

THE annual provincial meeting of the Fever Hospitals Group of the Society of Medical Officers of Health will be held at the City Hospital, Little Bromwich, Birmingham, at 3 p.m. on Friday, April 28th. Professor K. Douglas Williamson, cardiologist to the hospital, will read a paper and give a demonstration on the electro cardiograph in the study of the heart in diphtheria. Suitable trains leave Paddington at 11.10 a.m., and Euston at 11.30 a.m.

AN ordinary meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, April 27th, at 8.30 p.m., when a paper will be read by Dr. A. Kuyvett Gordon on the importance of the gonococcus in medico-legal investigations, which will be followed by a discussion.

THE Public Health and Housing Committee of the Essex County Council has issued invitations to the formal opening on Saturday, April 29th, at 3.15 p.m., of the new sanatorium at Black Notley, by the Minister of Health, and to the unveiling of a tablet in the King Edward VII Memorial Hall by Brigadier-General I. T. Wigan, on behalf of the Lord Lieutenant.

THE Jewish Health Organization of Great Britain has arranged a symposium on "Physical and mental aspects of the Jew," to be held at the Conway Hall, Red Lion Square, Holborn, W.C., on Sunday, May 25th, at 3.15 p.m. Sir Humphry Rolleston will preside, and the introductory papers will be read by Professor M. Ginsberg, Dr. L. Isserlis, Dr. W. M. Feldman, and Dr. E. Miller.

THE Gifford Edmonds prize in ophthalmology for the year 1930 for an essay on central scotoma, its pathology and clinical significance, has been divided between Rosa Ford, M.B., of London, and Laura M. Ligertwood, F.R.C.S., of Edinburgh.

THE Fellowship of Medicine announces that from April 22th to May 23th an intensive course in diseases of the throat, nose, and ear will take place at the Central London Throat, Nose and Ear Hospital. A four weeks' comprehensive course in psychological medicine will begin on April 23th at the Maudsley Hospital, Denmark Hill; in addition to lectures and demonstrations, the different forms of clinical instruction at the hospital will be open to those enrolling for the course. From April 22th to May 11th an afternoon course, under the direction of Dr. Eric Pritchard, will be given at the Infants Hospital, particularly for those engaged in infant welfare work; there will be clinics at the hospital and at other centres of interest. This course is limited to sixteen, and early application is desirable. From May 5th to 31st an afternoon course in dermatology will be given at St. John's Hospital comprising clinical instruction in the out-patient department, and lectures at 5 p.m. on certain dates; classes in pathology can be arranged if desired. From May 12th to 24th an all-day course will be given at the City of London Hospital for Diseases of the Heart and Lungs. Other courses in May include one for the M.R.C.P. examination, comprising evening lectures and demonstrations in ophthalmology, May 13th to July 4th; an afternoon course in ophthalmology at the Central London Ophthalmic Hospital, May 19th to June 13th; and one in diseases of children at the Hospital for Sick Children, May 26th to June 7th, if a minimum of twelve is obtained. An intensive course at Queen Mary's Hospital, Stratford, E.15, May 26th to June 7th, will consist of instruction in medicine, surgery, and in the special departments. Detailed syllabuses of all courses, including the general course, can be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course on diseases of the nervous system will be held at the National Hospital, Queen Square, W.C.1, from May 5th to June 27th. The course will consist of thirty-two clinical lectures and demonstrations at 3.30 p.m. each week-day except Wednesday and Saturday, instruction in the out-patient department on each week-day except Saturday at 2 p.m., and seven pathological lectures and demonstrations on Mondays at 12 noon. The fee for the course will be £6 6s. A course of eight lectures on the anatomy and physiology of the nervous system will be arranged on Fridays at 12 noon if there are enough applicants; fee £2 2s. A course of twelve clinical demonstrations on methods of examination of the nervous system will be given on Tuesdays and Thursdays at 12 noon; fee £2 2s. Applications should be addressed to the secretary, Medical School, National Hospital, Queen Square, W.C.1.

A REPORT of the proceedings of the conference on mental health held from October 30th to November 2nd, 1929, under the auspices of the National Council for Mental Hygiene in association with the joint committee of the National Council for Mental Hygiene and the Tavistock Square Clinic, has been published. The principal papers and addresses were summarized in the *British Medical Journal* of November 9th, 1929 (p. 863). Among those who attended the conference, which represented every branch of social work, were visitors from India, Australia, Tasmania, the United States, Canada, South Africa, and students from the International League of Red Cross Societies. The joint committee hopes to raise a substantial sum from the sale of this report for the work of the National Council and the Tavistock Square Clinic. Copies are obtainable at all booksellers, price 2s.

IN memory of the late Sir Baldwin Spencer, who was professor of zoology in the University of Melbourne, it has been decided to place a bronze medallion in the zoology library in the University. Mr. Paul Montford has been commissioned to prepare this medallion, and old students of Sir Baldwin Spencer are invited to contribute towards the cost, which will be 100 guineas. Donations should be sent to Sir Thomas Lyle, Lisbuoy, Irving Road, Toorak, S.E.2, Victoria, Australia.

AT a meeting of the Royal Sanitary Institute, on May 2nd, in the Town Hall, Tunbridge Wells, discussions will take place on "The maternity home as a health asset," and "Can the slum be abolished?" The chair will be taken at 5.30 p.m.

WE are informed that owing to the death of Professor Brailsford Robertson, editor of the *Australian Journal of Experimental Biology and Medical Science*, it has been found impossible to issue Part I of that periodical for 1939. A double issue, comprising Parts I and II, will be published in June.

SIR JOHN MARNOCH, K.C.V.O., Regius Professor of Surgery in the University of Aberdeen, has been appointed Deputy Lieutenant of the County of the City of Aberdeen.

THE annual congress known as the Journées Médicales de Lille will be held at Lille on May 24th and 25th.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963, and 9964* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology, Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocrity Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bicuspid, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

MISSED LABOUR.

DR. H. JULYAN HOYTE (Elizabethville, Katanga) writes: An elderly woman came out to Katanga in 1927, was married the same year, and in March, 1928, went to a nursing home for her confinement. I am told that labour commenced about full term and after a normal pregnancy, but ended after continuing for some hours. Following this the foetal movements ceased, and nothing further took place for two months, when labour was induced, and she was delivered of a macerated foetus. She is again pregnant, and I should be glad to be informed whether a repetition of the former experience is probable. If so, what line of treatment should be adopted?

INFANTILE SEBORRHOEIC ECZEMA.

"E. B.," answering the query of "M.B., Ch.B." (March 15th, p. 524), suggests that the 9 months' old child should be weaned entirely. The bowels should be kept open by a daily dose of syrup of figs, prune juice, or, if these are not effectual, by liquid paraffin. The head must be kept covered with muslin, which is changed frequently, and the child's arms be lightly splinted with cardboard to prevent scratching. Zinc ointment and ung. hyd. ammon. dil. will then probably be all that is necessary if the starch and sugar intake is regulated in the diet.

INCOME TAX.

Allowance for Cars.

"C. H." has for some years kept two cars—"a good one, and a cheap one." The car which formerly fell under the first category has now become too old for reliable service and the cheaper car was sold in March, 1929, for £120 (its written-down value then being £191), and a new car bought for £445. What can he claim?

*** (1) Obsolescence allowance: as an expense of the practice during the year ended March 31st, 1929, £191 − £120 = £71. (2) Depreciation allowance for 1930-31 on £255 (the written-down value of the original "good" car) plus £445—that is, 15 per cent. on £700=£105. A point to be watched in future is that obsolescence allowance should be claimed when the old car is sold and a new (cheap) one bought. The amount to be claimed, if that transaction takes place in 1930-31 will be £255−£38=£217, less the amount of the allowance received on purchase of the new car, say £20, net claim £197, or the cost of the new car, whichever is the less.

Bad Debts.

"H. H. C." explains that in 1929 his gross bookings amounted to £3,600 and his allowable expenses to £1,000. Of the £3,600 booked, £400 is still outstanding, and £320 is probably irrecoverable. What is his liability?

*** In our opinion £3,600−£320−£1,000=£2,280, but the Revenue authorities usually object to round-figure estimates of bad debts in terms of percentages. The Income Tax Act of 1918 provides for an allowance for "doubtful debts to the extent that they are respectively estimated to be bad." The word "respectively" is held—and probably correctly held—to imply a valuation of each outstanding debt separately. We therefore advise "H. H. C." to reconstruct his statement of claim to the deduction of £320 for bad and doubtful debts on the separate valuation basis, and file a list of the separate amounts (not names) with the local inspector of taxes; he may then realize that the amount so claimed is admissible.

Motor Car Renewal.

"J. M. C." bought a 10-h.p. car for £300 in 1922. In 1929 he sold it for £55, and bought a smaller car for £145. What relief is he *entitled* to?

*** He can deduct as an expense of the year 1929 the actual out-of-pocket expense—that is, £145−£55=£90, and no more. It is a pity our correspondent did not claim depreciation allowance in the past; he could not have lost by it, and, in fact, would have gained.

LETTERS, NOTES, ETC.

GLASS PERMEABLE TO ULTRA-VIOLET RAYS.

WITH the following extracts from a long letter sent by Mr. G. L. Pilkington, in reply to Dr. Dyson (March 22nd, p. 576), we must bring the correspondence on this subject to a close: Dr. Dyson adopts the fallacy of quoting experiments with a mercury vapour lamp as a means of assessing the value of natural sunlight. The energy of sunlight is concentrated in the region of the longer wave-lengths, whereas that of the mercury vapour lamp is concentrated in the region of the shorter wave-lengths, and as many of the materials are far more permeable to the longer ultra-violet radiations than to the shorter, surely this factor of energy distribution, which Dr. Dyson ignores, is as important as the factor of intensity of radiation. The figure "one-sixth of the body," quoted by Dr. Dyson from the work of Hill and Eldinow, represents not the minimal area necessary to produce a minimal response, but the area necessary to produce a maximum response—a very different matter. His statement that "Less than this, they proved, not only did not increase its power, but actually decreased it," is puzzling; we can find no reference to such a phenomenon in the literature, and it is difficult to understand how any stimulus to the skin that does not reach a threshold value could possibly result in a depressant action. In any case, the experiments under discussion, valuable as they are in relation to phototherapy, are not necessarily strictly applicable to heliotherapy. The shorter rays of the mercury vapour lamp have a rapid lethal effect on the surface cells of the skin, and the cells which are killed are coagulated, and thus the permeability of the skin is rapidly reduced. The ultra-violet portion of sunlight, however, has a comparatively insignificant lethal effect, and so this barrier of coagulated cells is not formed and maximum absorption of the rays occurs. Furthermore, the effective depth of penetration of sunlight would be greater than that of radiations from the mercury vapour lamp.

PREVENTION OF DENTAL DISEASE.

MR. J. MENZIES CAMPBELL, D.D.S., F.R.S.Ed. (Glasgow), in the course of a letter, writes: Are the results obtained by school dental clinics commensurate with the vast sums of money that is spent on them? And, if not, how can such money be spent to better advantage? It has long been held that the only means for reducing the incidence of dental caries is by careful brushing of the teeth and the filling of carious cavities. At present in Great Britain alone there are over 14,000 dentists attending to the teeth of the people, yet all this specialist treatment has not reduced to any appreciable extent the incidence of dental caries. Dental services, public and private, have not yielded sufficiently satisfactory returns; symptoms alone have been treated, but the causes have not been found and removed. The recent work of Mrs. Mellanby, Howe, Toverud, and others has proved that the structure of the child's teeth depends on the food taken by the expectant mother; in other words (as I have stated in a recent publication), "the diet of the expectant mother is the alpha and the omega of preventive dentistry." This fact becomes apparent when it is realized that for several months before the child is born all the temporary and most of the permanent teeth are already present in its jaws. Not only can decay be prevented by proper attention to the mother's diet, but later it can be arrested by attending to the diet of the children themselves. I suggest that it would yield more satisfactory returns if school dental clinics were abolished and the money so saved were expended on the proper feeding of expectant mothers and children. The results would more than justify this apparently revolutionary step; not only would the incidence of decayed teeth be reduced to a minimum, but the resistance of children would be so raised against disease that money would be saved on the school medical services.

CAESAREAN HYSTERECTOMY IN OSTEOMALACIA.

IN the course of a letter referring to the article by Dr. Bethel Solomons on Caesarean hysterectomy (*Journal*, March 29th, p. 584), Dr. Janet M. C. Gray (Lewisham) reports that nearly all the midwifery in her experience has been performed in India, and, with the exception of one case, all the patients requiring hysterectomy were affected with osteomalacia. They never came under observation until pregnancy was advanced, or labour had actually commenced, and sometimes only when the uterus had ruptured and the child was dead. To patients admitted before labour had started dietetic treatment was given in hospital, and in later years tablets of the parathyroid and anterior pituitary extracts were administered, since they seemed to have a marked influence on the severe pain of the disease. Dr. Gray states that she performs Caesarean hysterectomy at full term, removing the uterus, since pregnancy rapidly increases the pains and deformities of osteomalacia. She adds that this disease is almost as common in the United Provinces among the Hindus as among the Mohammedans, the Hindu women in this part of the country keeping strict purdah.

MEDICAL TREATMENT IN NORTHERN BRITISH COLUMBIA.

MISS F. H. EVA HASELL, organizer of the Church of England Sunday School caravans in Western Canada (Dacre Lodge, Penrith, Cumberland), writes: While visiting isolated British settlers in Northern British Columbia (including the Peace River district) last summer, I found 500 people living south of François Lake cut off from any medical attention during the winter months, and 1,000 people north of the Peace River in similar circumstances. I interviewed the Minister of Health for British Columbia on the matter, who said he had been trying for a year to get doctors for those parts, but had failed. He is willing to accept a British doctor (man or woman), but can only offer them a subsidy of £80. The settlers would provide board and lodging. I will guarantee £50 for expenses out, and would be glad to receive all applications and give information.

POSITIVE SPUTUM IN ACUTE MILIARY TUBERCULOSIS.

DR. W. E. ROPER SAUNDERS (Chester-le-Street) writes: It is often stated that, even if a specimen of sputum is obtainable in acute miliary tuberculosis, it is usually negative for tubercle bacilli. Particulars are given, therefore, of a case in which a child, aged 3 years and 4 months, had a positive sputum. The illness commenced in January with cough. Rhonchi were audible, and the case was considered to be one of bronchitis. The symptoms did not, however, improve, and the temperature began to swing daily from 99° to 103° F. A sputum test on February 28th proved to be positive. When examined on March 8th generalized rhonchi were present, but at the extreme apex of the right lung mobility was slightly impaired, with impairment of the percussion note, and a few fine rales were audible in the same area. Death occurred on March 18th.

SCREW-CAP BOTTLES.

THE rustless white enamelled screw caps used in the U.G.B. medical bottle service are described and their advantages set out in the spring number of the *Bottle and Glass Container Bulletin*, issued by the United Glass Bottle Manufacturers, Ltd., 40-43, Norfolk Street, Strand, E.C.2.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 164.

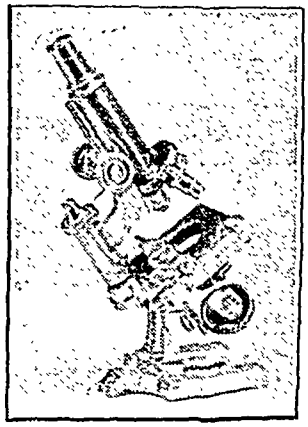
Every instrument overhauled and guaranteed optically and mechanically perfect.



A LIMITED NUMBER NOW OFFERED AT ONE-HALF MANUFACTURERS' PRICES.

£35 ROSS MICROSCOPES

(as illustrated).

Complete in Polished Wood Lock-up Case FOR **£18 : 10 : 0** each.

Very handsome models fitted with mechanical stage, giving vertical movement of 30 mm. and diagonal traverse of 60 mm. Drawtube carries eyepieces of 23.2 mm. gauge. Fitted coarse and fine adjustments, Abbé condenser, and iris diaphragm. Triple nosepiece. Eyepieces Nos. 2 and 4. Objectives $\frac{1}{6}$", $\frac{2}{3}$" and $\frac{1}{12}$" oil-immersion.

GOVERNMENT SURPLUS MICROSCOPES.

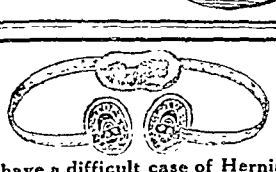
£45 BAKER MICROSCOPES *(not illustrated)*

Complete in Polished Wood Lock-up Case FOR **£21 : 0 : 0** each.

General description. Designed to meet all requirements in the bacteriological laboratory, fitted with mechanical stage which is secured to a substantial platform cast on the limb, ensuring rigidity, giving vertical movement of the entire stage of 20 mm. and diagonal traverse of a clear 60 mm. by a scale divided to 1.0 mm. reading by Vernier to 0.1 mm. The whole can be removed, leaving a large plain stage for the examination of Petri dishes or large sections. The substage slide is also part of the limb, and is an improvement over those secured to the underside of the stage. The body is provided with a drawtube carrying eyepieces of the 23.2 mm. gauge.

Complete specification as follows:—STAND AS DESCRIBED ABOVE, with Abbé condenser and iris diaphragm; triple nosepiece; eyepieces, 2, 4; objectives, $\frac{1}{6}$", $\frac{2}{3}$", and $\frac{1}{12}$", oil-immersion N.A. 1.30; magnification from 53 to 500.

Complete list of all other models and accessories available on application.



GENERAL PRICE LIST OF SURGICAL INSTRUMENTS, ASEPTIC FURNITURE and SUNDRIES forwarded immediately on request. Enquiries cordially invited for all requirements.

INDIVIDUAL TRUSSES ONLY SUPPLIED.

That part of our Surgical Service relating to the supply of "trusses" is a well-known success.

This is due, in our opinion, to our knowledge in correctly interpreting doctor's instructions and also the fact that every truss we supply is an "*individual*" truss in the true sense.

We keep a stock of several thousands of hand-made springs of different gauges and tempered in varying strengths. In addition, we have pads of many shapes and sizes. From these components we "*build*" the truss and cover it as required.

In all cases our aim is to make an "*individual*" truss for each patient, suitable in fit, quality, and price.

Illustrated price List with measurement forms sent on request.

A Remarkable advance in the presentation of H_2O_2

Also in exactly similar form and price—
SOLID IODINE

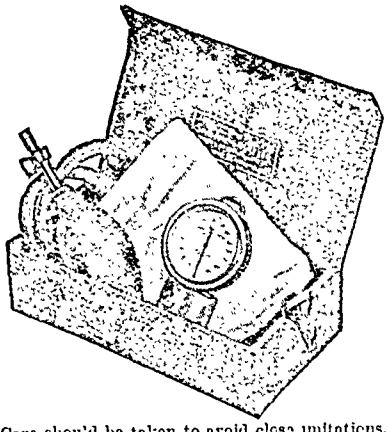
Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.
Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.
A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 93, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'
SOLIDIFIED PEROXIDE OF HYDROGEN
in neat, handy glass tubes.

DIABETES

Brusson Bread, which has the lowest starch content of any starch-reduced gluten bread, provides a scientific aid in adjusting the carbohydrate to the patient's tolerance. Its scientifically graded content of starch, protein, and fat enables the physician to prescribe the correct quantity for each patient.



Liberal samples free to Medical Men on request. Also a copy of "The Amplified Diet in Diabetes," often very useful for giving to patients.

Apply to Superintendent.

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.

Care should be taken to avoid close imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms etc., apply to the Medical Superintendent.*

THE JOINT NURSING AND MIDWIVES COUNCIL ACT (NORTHERN IRELAND), 1922.

NOTICE IS HEREBY GIVEN that an Election of Eight Members of the Joint Nursing and Midwives Council for Northern Ireland will be held in the year 1930.

1. *The day of election will be 17th day of June, 1930.*

2. (1) The following table shows the numbers and qualifications of the persons to be elected, and the qualifications of the persons entitled to nominate and take part in the election of each class of candidate.

Number of persons to be elected.	Qualifications of persons to be elected.	Qualifications of persons entitled to nominate and take part in the election.
2	Registered Medical Practitioners.	Registered Medical Practitioners practising in Northern Ireland.
4	Persons who are or have at some time been Nurses actually engaged in rendering services in direct connection with the nursing of the sick.	Registered Nurses—*i.e.*, Nurses registered on the Register of Nurses for the Sick in Northern Ireland.
2	Persons who are or have at some time been Nurses actually engaged in rendering services in direct connection with the nursing of the sick and are qualified midwives.	
Total 8		

(2) In order to be eligible for election or to be entitled to nominate for and take part in the election, a person must have the requisite qualifications on the 15th day of May, 1930.

3. (1) Each candidate for election must be nominated in writing and the nomination paper must be delivered to me by post or otherwise at the office of the Joint Nursing and Midwives' Council for Northern Ireland, 118, Great Victoria Street, Belfast, before the hour of noon on the 15th day of May, 1930. The name of more than one candidate shall not be inserted in any one nomination paper.

(2) *Every nomination paper* must state the surname and other names in full of the candidate and his or her registered address and registered qualification or qualifications. It must be signed by not fewer than six persons having the requisite qualifications for nominating the candidate, two of whom must sign as proposer and seconder respectively, and the address and registered qualification or qualifications of each such person so signing must be appended.

(3) The nomination paper must be accompanied by a consent in writing signed by the person nominated acknowledging that such person consents to be nominated, and shall be signed by two accredited persons who shall state their respective residence and profession or occupation.

(4) Any person having the requisite qualifications for nominating a candidate may nominate any number of candidates not exceeding the number to be elected.

4. Forms of nomination papers and of consent to nomination may be obtained free of charge from me on application by post or otherwise by persons having the requisite qualifications for nominating a candidate, but no such person will be entitled to obtain more nomination papers or form of consent to nomination than there are persons to be elected.

5. Any candidate for election may, before the hour of noon on the 15th day of May, 1930, withdraw his or her candidature by allowing or causing to be delivered at the office of the Joint Nursing and Midwives Council, a notice in writing of such withdrawal signed by the candidate.

6. If the number of candidates of any class who are deemed to have been validly nominated, and whose candidature is not withdrawn, exceeds the number of persons of that class to be elected, I will cause, not later than the 1st day of June, 1930, a voting paper and an identification envelope to be sent to each person qualified to take part in the election.

Dated this 11th day of April, 1930.

W. R. DAWSON,
Returning Officer.

Ayrshire (Glenafton) Sanatorium

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (men) for the above post. Preference will be given to candidates who have had experience in Tuberculosis and the Diseases of Children.

The salary will be £650 per annum, rising by annual increments of £25 to £700, with £60 per annum for travelling expenses, and will be subject to the usual deductions under the Local Government and Other Officers Superannuation Act, 1922.

The appointment, which will be subject to one month's notice and to the approval of the Government Departments concerned, will be a whole-time appointment under the direction of the Medical Officer of Health and School Medical Officer. The person appointed to the post will not be allowed to engage in private practice.

The duties will relate principally to School Medical Inspection and Treatment and Tuberculosis Clinics, but the person appointed will be expected to assist the Medical Officer of Health generally.

Personal canvassing of Members of the Council is prohibited.

Applications, on forms to be supplied from this office, should be sent to me on or before April 30th, endorsed "Appointment of Assistant Medical Officer, etc."

Town Hall, Bournemouth. HERBERT ASHLING, Town Clerk.
April, 1930.

County Borough of Sunderland.

ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

Applications are invited from fully qualified men and women for the position of Assistant Medical Officer for Maternity and Child Welfare.

Applicants must be registered Medical Practitioners, have had at least three years' experience in Public Health work since qualification, be able to show special experience in Ultra-violet Irradiation treatment, and hold a Diploma in Public Health.

Salary £600 per annum.

The appointment is subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical test as required by the Council for the purpose of that Act.

Applications, stating age, qualifications, and experience in Maternity and Child Welfare work, together with not more than three recent testimonials, should be delivered to the undersigned not later than Monday, April 21st, endorsed "Medical Officer."

Canvassing, directly or indirectly, until after the first selection of candidates, will disqualify.

Town Hall, Sunderland. H. CRAVEN, Town Clerk.
March 31st, 1930.

Borough of Wednesbury.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Town Council invite applications for the appointment of Medical Officer of Health, School Medical Officer, Maternity and Child Welfare Officer, and Superintendent of the Corporation's Hostel for Ailing Babies, for the Borough of Wednesbury.

Salary £800 per annum, rising by biennial increments of £50 to £900 per annum.

Applicants, *being fully qualified and duly* qualified registered Medical Practitioners, must have such additional qualifications as are prescribed in the Sanitary Officers Order, 1926.

The appointment will be made in accordance with the provisions of the Public Health (Officers) Act, 1921, the Sanitary Officers Order, 1926, and the orders and directions of the Council, and will be subject to the approval of the Minister of Health and the Board of Education.

The officer appointed will be required to devote his whole time to the duties of the position, and to reside within the Borough.

Applications, accompanied by copies of not more than three recent testimonials, must be sent to the undersigned on or before May 5th, endorsed "Medical Officer of Health."

Town Hall, Wednesbury. N. P. LESTER, Town Clerk.
April 12th, 1930.

Lowestoft and North Suffolk Hospital, Lowestoft.

JUNIOR HOUSE SURGEON (male) required. Salary £120 per annum, with board, residence, and laundry. Duties to commence in April. Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

Applicants must be registered Medical Practitioners, have had at least three years' experience in Public Health work since qualification, be able to show special experience in Ultra-violet Irradiation treatment, and hold a Diploma in Public Health.

Salary £600 per annum.

The appointment is subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to a medical test as required by the Council for the purpose of that Act.

Applications, stating age, qualifications, and experience in Maternity and Child Welfare work, together with not more than three recent testimonials, should be delivered to the undersigned not later than Monday, April 21st, endorsed "Medical Officer."

Canvassing, directly or indirectly, until after the first selection of candidates, will disqualify.

Town Hall, Sunderland. H. CRAVEN, Town Clerk.
March 31st, 1930.

Borough of Wednesbury.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Town Council invite applications for the appointment of Medical Officer of Health, School Medical Officer, Maternity and Child Welfare Officer, and Superintendent of the Corporation's Hostel for Ailing Babies, for the Borough of Wednesbury.

Salary £800 per annum, rising by biennial increments of £50 to £900 per annum.

Applicants, being fully qualified and duly qualified registered Medical Practitioners, must have such additional qualifications as are prescribed in the Sanitary Officers Order, 1926.

The appointment will be made in accordance with the provisions of the Public Health (Officers) Act, 1921, the Sanitary Officers Order, 1926, and the orders and directions of the Council, and will be subject to the approval of the Minister of Health and the Board of Education.

The officer appointed will be required to devote his whole time to the duties of the position, and to reside within the Borough.

Applications, accompanied by copies of not more than three recent testimonials, must be sent to the undersigned on or before May 5th, endorsed "Medical Officer of Health."

Town Hall, Wednesbury. N. P. LESTER, Town Clerk.
April 12th, 1930.

Lowestoft and North Suffolk HOSPITAL, LOWESTOFT.

JUNIOR HOUSE SURGEON (male) required. Salary £120 per annum, with board, residence, and laundry. Duties to commence in April. Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

Administrative County of LONDON.

The LONDON COUNTY COUNCIL invites applications for the position of JUNIOR ASSISTANT MEDICAL OFFICER (man or woman) in the Public Health Department, for duty at QUEEN MARY'S HOSPITAL FOR CHILDREN, CARSHALTON, SURREY. Candidates must be qualified by law to practise both Medicine and Surgery in England. The salary is £500 a year, which is subject to review. The candidate appointed will be required to reside in the Hospital and to pay for board, lodging, and washing at the rate (at present £130 a year) fixed from time to time.

In the case of women, marriage terminates contract of service.

Application forms containing full details obtainable (stamped addressed foolscap envelope necessary) from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1, to whom they must be returned by April 24th. Canvassing disqualifies.

The County Hall, Westminster Bridge, S.E.1. MONTAGU H. COX, Clerk of the London County Council.

Borough of Luton.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Luton Borough Council invite applications for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer. Salary at the rate of £600 per annum. No bonus will be paid.

The gentleman appointed will be required to devote the whole of his time to the duties, and to act under the direction of the Medical Officer of Health.

On receipt of stamped and addressed envelope, the undersigned will supply particulars of the appointment and application form.

Applications (on such form), accompanied by copies of not more than three recent testimonials, endorsed "Assistant Medical Officer of Health," must be delivered to me by not later than Wednesday, April 23rd.

Canvassing is prohibited and will disqualify.

2, Upper George St., Luton. W. SMITH, Town Clerk.
April 12th, 1930.

City and County of Bristol.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council invite applications for a whole-time Assistant Medical Officer of Health. Age not exceeding 40 years. Salary £600 per annum. The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The duties will consist principally of examination of children in the Council's Secondary, Elementary, and Special Schools, treatment in School Clinics, etc., but the officer appointed will also be required to work in all departments of the Medical Officer of Health of the City and Port.

Applications, which must be on a form provided for this purpose, should be accompanied by not more than three recent testimonials, and must be received by the undersigned not later than Monday, May 5th. Envelopes should be endorsed "Assistant Medical Officer of Health."

Canvassing will disqualify.

Council House, Bristol. JOSIAH GREEN, Town Clerk.
April 12th, 1930.

The Royal Borough of KENSINGTON.

THE LOCAL GOVERNMENT ACT, 1929.

VACCINATION.

The Council of the Royal Borough of Kensington invite applications from local Medical Practitioners who are duly qualified in Vaccination work and who are willing to enter into contracts for Public Vaccination in the Districts of North and South Kensington respectively.

The duties will be in accordance generally with the provisions of the Vaccination Order, 1930, and subject to the approval of the Minister of Health, and the fees payable will be those laid down by the Vaccination Order with the exception that the payment authorised by Section 5 (1) (a) of the Order shall be 1s. 6d. instead of 1s. A copy of the Vaccination Order may be inspected at the Town Hall.

The contracts will be terminable by twenty-eight days' notice on either side.

The successful candidates will not be regarded as officers of the Council, and will not be subject to any superannuation provisions.

Applications must be delivered to me not later than Wednesday, April 23rd.

Town Hall, Kensington, W.8. HORACE RAPSON, Town Clerk.

APPOINTMENTS.—Contd.

Bristol Eye Hospital.

Applications are invited for the post of JUNIOR HOUSE SURGEON. Salary £100 per annum. Full particulars may be obtained from the Secretary.

Applications and testimonials to be received by Monday, May 5th.

House Surgeon, male, wanted immediately for HUNTINGDON HOSPITAL. Salary £125 per annum and laundry. Temporary, also to Dr. GRAHAM, County Hospital, Huntingdon.

Leicester Royal Infirmary.

HONORARY SURGEON.

A vacancy will occur on June 1st for an Honorary Surgeon, consequent upon the retirement, under the Rules, of Mr. Cecil Marriott, M.Ch., F.R.C.S., Senior Honorary Surgeon. Applications are invited for the post. Past and present members of the Assistant Honorary Staff are primarily eligible for election to full Staff appointments. The Senior Honorary Assistant Surgeon, Mr. R. S. Lawson, F.R.C.S., is an applicant.

HONORARY ASSISTANT SURGEON.

Under the above announcement, a vacancy is expected for an Honorary Assistant Surgeon. Candidates should be Fellows by examination of the Royal College of Surgeons of England, or Graduates in Surgery of one of the Universities of the United Kingdom or Ireland. A grant of fifty guineas annually is made for out-of-pocket expenses. Applications (accompanied by 100 copies of testimonials) to reach the undersigned by Monday, May 12th. The appointment will be made on May 15th.

Canvassing for appointments is not allowed.

HARRY JOHNSON,
April 14th, 1930. House Gov. & Sec.

The Middlesex Hospital and MEDICAL SCHOOL, W.1.

Applications are invited for One MEDICAL REGISTRARSHIP. The Registrars are attached to Clinical Units of the Hospital and are responsible for the clinical notes, the carrying out of clinical and pathological examinations, the preparation of material for demonstration, and the co-ordination of the work in the Bland-Sutton Institute of Pathology with that in the Wards.

The appointment will be from May 16th to December 31st, and the holder is eligible to apply for re-appointment and may retain office for three consecutive years. Salary £300 per annum. He is required to attend at the Hospital daily from 10 to 5. Further particulars may be obtained from the Secretary-Superintendent, to whom applications, with not more than three testimonials, must be sent by noon on Monday, May 12th

By Order of the Board,
S. R. C. PLIMSOLL,
Secretary-Superintendent.

Salford Royal Hospital. (265 Beds.)

Applications are invited for the following vacancies in the Resident Medical Staff (male):

HOUSE PHYSICIAN. Salary at the rate of £125 per annum.

CASUALTY HOUSE SURGEON. Salary at the rate of £125 per annum.

The appointments are for a period of six months, with board and residence.

Candidates must be registered under the Medical Acts.

The Hospital has the approval of the Royal College of Surgeons of England, and appointments here are recognized for the English Fellowship (Final).

Forms of application, which may be obtained from the undersigned, must be delivered at once.

By Order of the Board,
Salford Royal Hospital. GEORGE RUDDLE, Gen. Supt. & Secretary.
April 14th, 1930.

The Royal Hospital, WOLVERHAMPTON.

(Incorporated under Charter.) (300 Beds.)

There will be a vacancy for an HONORARY ASSISTANT SURGEON in January, 1931.

Applications for the post are invited and must be received on or before May 6th. Candidates must possess qualifications suitable for an important surgical position on the staff of a large modern Hospital, and must have actual experience of major operative surgery.

The appointment will be made on May 13th, but the candidate appointed will not be required to take up his duties until the post becomes vacant in January, 1931.

Further particulars on application to—

W. H. HARPER,
April 14th, 1930 House Gov. & Sec.

Royal Waterloo Hospital for CHILDREN AND WOMEN, Waterloo Road, S.E.1.

There will be a vacancy on May 1st for a HOUSE SURGEON (male) at the above Hospital. The appointment is in the first instance for a period of six months. Salary at the rate of £100 per annum, with board and residence. Applications, with copies of testimonials, should be forwarded not later than Thursday morning, April 24th, to the Secretary at the above address, from whom further particulars can be obtained.

Addenbrooke's Hospital, CAMBRIDGE.

Applications are invited for the following posts:

(a) HOUSE PHYSICIAN;
(b) HOUSE SURGEON No. 2.

Each appointment is tenable for a period of six months, but is terminable at an earlier date by one month's written notice on either side.

The salary of each officer will be at the rate of £130 per annum, with board, residence, and laundry.

Candidates (male), who must be unmarried and [illegible] requested to forward their age, qualifications, etc., of not more than four testimonials, to the undersigned, as soon as possible.

W. H. HEAD, Secretary-Superintendent.

The Royal Infirmary, SHEFFIELD.

The Weekly Board invite applications for the post of ASSISTANT CASUALTY OFFICER. The appointment will terminate on June 30th next, but the officer selected will be eligible for re-election or for one of the other twelve House appointments. The salary attached to the post is £80 per annum, rising after six months' service to £100 per annum, together with board and residence. Applications, together with copies of testimonials, to be sent to the undersigned immediately.

Board Room, JNO. W. BARNES, F.C.I.S.,
April 14th, 1930. Gen. Supt. & Sec.

Stockton and Thornaby Hospital, STOCKTON-ON-TEES. (140 Beds.)

Applications are invited for the post of JUNIOR RESIDENT MEDICAL OFFICER (male). Salary £150, with board, residence, and laundry.

Candidates for the above post must be doubly qualified and unmarried, and are required to commence duties on or about May 1st.

Application, stating age, nationality, and experience, together with copies of three recent testimonials, to be sent to the undersigned as early as possible.

J. WILKINSON, Secretary.

Leith Hospital (Incorporated).

The Managers invite applications for the following posts, from now till October 1st:

(1) JUNIOR HOUSE PHYSICIAN, and
(2) RESIDENT MEDICAL OFFICER for the Children's Wing. Board, residence, and laundry are provided.

Applications, with copy testimonials, to be sent to—

R. BEVERIDGE SMITH, W.S.,
10, Mill Lane, Leith. Hon. Secretary.

Hounslow Hospital, Staines Rd., HOUNSLOW, MIDDX. (70 Beds.)

Wanted, SENIOR MALE HOUSE SURGEON. Salary £120 per annum, with board, residence, etc. The appointment will be for six months.

Applications, stating qualifications, age, and experience, and enclosing two copies of testimonials, should be sent (marked "House Surgeon," top left-hand corner) to W. T. Ross, Secretary, Hounslow Hospital.

Durham County Hospital.

The post of JUNIOR HOUSE SURGEON will be vacant on April 30th. The appointment is for six months certain. Candidates must be male and duly qualified and registered. Number of beds 75. Salary £120 per annum, with board and lodging. Applications, with copies only of testimonials, to be sent to the undersigned by April 23rd.

79, Saddler Street, Durham. WM. R. WILSON, Secretary.

Queen's Hospital for Children, Hackney Road, London, E.2.

CASUALTY OFFICER required on June 1st. Six months' appointment. Salary £100 a year, with board, residence, and washing. Preference given to candidates who have previously held resident appointments. Applications must be made on forms to be obtained from the Secretary, and must be sent in, with copies of not more than four testimonials on or before April 28th.

T. GLENTON-KERR, Secretary.

Worthing Hospital.

Applications are invited for the posts of Two HONORARY OPHTHALMIC SURGEONS.

Applications, with copies of testimonials, to reach the Secretary on or before the 28th inst.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,

Tele. Address: Triform, Wesdo—London.

Oxford Street, W.1.

Telephone: Mayfair 1783 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Detached house in half an acre of garden, 2 reception, 5 bedrooms, etc. Rent £55 p.a. Hunting, golf, etc., and first-class schools within reach. Premium £1,500.
3. WITHIN FOUR MILES OF THE BANK.—Old-established good working-class PRACTICE, showing a steady average of £1,290 p.a., including panel of over 1,600. Advice and medicine from 2/-. Suitable house in good repair, with 3 bedrooms, bathroom, etc. Electric light. Garage. Rent on lease £104 p.a. Premium £2,250.
4. LONDON, EAST.—P[illegible] one-half share is for disposal in an old-established [illegible] and panel Practice, averaging about £2,800 p.a. Panel of 5,000. Visits 2/6 to 5/6. Very suitable small house, with 3 bedrooms, bathroom, etc. Garden. Rent on lease £50 p.a. Premium £2,500.
5. WITHIN TWELVE MILES OF LONDON.—In a rapidly developing residential district, offering exceptional future prospects, a mixed-class PRACTICE, averaging at the rate of £500 p.a., and increasing. Panel about 100. Visits 5/- and 7/6. Nearest opposition 2 miles. Very good detached corner house, with garden. Price, freehold, £1,800 (£1,200 on mortgage). Moderate premium.
6. LADY DOCTOR'S PRACTICE.—KENT.—Within 40 miles of London. In a town of 100,000 a well-established middle and working-class Practice, worth last year £850, including panel of 200. Visits 3/6 upwards. Mids. from 3 gns. (20 cases yearly). House, with good accommodation. Rent on lease (15 years to run) £65 p.a. Premium £1,200. Practice equally suitable for Medical Man.
7. ATTRACTIVE SOUTH COAST TOWN AND SEASIDE RESORT.—PARTNERSHIP.—Half share of old-established and increasing mixed-class Practice, averaging £2,300 p.a. (last year £2,527), with view to ultimate succession if desired. Appts. worth over £75 and panel of 1,500. Visits 5/- to 2 gns.; very few cases. Good house, with ample accommodation, at moderate rental. Premium 2 years' purchase. Held by Vendor over 30 years.
8. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
9. LONDON, S.W.—RIVERSIDE SUBURB.—Well-established mixed-class PRACTICE, averaging about £1,200 p.a., incl. panel of 850. Fees 2/6 to 7/6. No mid. Very easily worked, and good scope for enlargement. Suitable house, 6 rooms in addition to kitchen, bathroom, and professional accom. Rent on long lease, £100 p.a. Prem. £2,000.
10. DUNDEE.—Well-established PRACTICE in good residential area, offering large scope particularly for panel and midwifery. Income last year over £750 and increasing. Very well situated house, with ample accom. Price £2,800 or can be rented. Prem. £750 or near offer.
11. YORKS.—In a clean and thriving manufacturing town, an old-established Homœopathic and partly Allopathic PRACTICE, held about 50 years by Vendor who is retiring. Cash receipts for the past three years average £2,400 p.a. Patients middle and better-class. Midwifery refused. Good house available, rent £100 p.a. Premium only one year's purchase, part down and balance by arrangement.
12. SURREY.—Attractive residential district within 20 miles.—Mixed-class PRACTICE producing about £700 p.a., but capable of much increase, as neighbourhood is developing. Panel of 500. Fees 2/6 upwards. Very nice house, with 3 reception, 8 bedrooms, and three acres of garden. Rent on lease £165 p.a. Smaller house available if desired. Premium £1,200.
13. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
14. YORKS.—PARTNERSHIP.—A one-third share, with increase later, is offered in a sound and increasing middle and working-class Practice, situated in prosperous district close to two good towns. Average gross cash receipts for past three years £3,226 (last year £3,354). Panel of 2,100, and appts. worth over £130. Good house, with 2 reception, 4 bedrooms, etc. Large garden and paddock. Garage. Price £1,900. Premium for share 1½ years' purchase.
15. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—Old-established mixed general PRACTICE. Average income nearly £1,900. Panel of 2,500. Fees 2/6 to 7/-. No mids. No Assistant kept. Well-situated house, with good accommodation. Rent on lease £120. Prem. £3,300.
16. WITHIN 40 MILES OF LONDON.—In a thriving Riverside and Hospital town (pop. over 40,000).—Old-established mixed-class and increasing PRACTICE worth over £2,300 last year, including panel of 1,600 to 1,700. House contains professional accommodation, 2 reception, 4 bedrooms, bathroom, etc. Small garden and garage. Rent on lease £60 p.a. Premium £3,650, to include good book debts of £500, drugs, etc., and consulting room and surgery furniture.
17. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACTICE averaging for the past three years £904 p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). Very little midwifery. One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, bathroom, etc.). Large garden and garage. Water laid on and gas plant installed. Rent £50 p.a. Premium £1,400. Excellent sport.
18. PARTNERSHIP.—WEST MIDLANDS.—The Third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional beauty. Cash receipts average £2,367 p.a., including panel of 1,084. Opposition not strong. Expenses light. Choice of two houses (small) which can be bought for £600 or £700. Premium 2 years' purchase.
19. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1½ acres. Price, freehold, £3,500. Premium 1½ years' purchase.
20. SOUTH-WEST OF ENGLAND.—Old-established and increasing PRACTICE in pretty district 5 miles from Hospital town and within 10 miles of the sea. Income last year £1,489, including Union, etc. (£105) and panel of 780. Railway station near. Detached house (professional rooms, 2 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Rent on lease £45 p.a. Premium £2,100.
21. WITHIN FIFTY MILES OF LONDON.—In a pretty residential district, a well-established PRACTICE averaging over £700 p.a., including panel of 538, and appts. worth about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Elec. light. Price for freehold £3,000. Premium £1,050. Exceptionally good educational facilities for boys.
22. LARGE UNIVERSITY CITY (WEST).—Good-class old-established non-dispensing PRACTICE worth last year £1,274, including select panel of about 350. Visits up to 21/-. Very little midwifery. Good house in best part of City, overlooking park, with ample accommodation. Vendor's freehold, but will be let on lease. Premium only £1,200.
23. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, experienced, 30 to 35 years of age and married preferred) can acquire a share (producing at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house, with ample accommodation, garden, etc., on rental. Premium 2 years' purchase. Short preliminary assistantship essential.
24. SOUTH-WEST OF ENGLAND.—GOOD HOSPITAL TOWN.—A one-half share in an old-established mixed-class PRACTICE is offered owing to the retirement of the Junior Partner. Gross cash receipts average £2,300 p.a., including good appts. Small panel. Low expenses. Commodious house, with garden and garage, rent £70 p.a. Premium 2 years' purchase. Vendor on staff of Hospital, and scope for surgery.
25. YORKS.—LARGE TOWN.—Very old-established middle and working-class PRACTICE, offering exceptional scope for increase. Income for last year £1,500, including panel of over 1,700. Visits 4/6 to 5/-. Conveniently situated house, with 2 reception, 4 bedrooms, etc. Rent on lease £56 p.a. Premium £2,250.
26. SOUTH DEVON.—PARTNERSHIP.—Attractive Town close to sea.—A half share in very old-established and rapidly increasing mixed general Practice. Average cash receipts last 3 years £2,727, last year £3,521. Panel of 1,150. Fees 3/6 to 21/-. Good house in its own grounds with ample accommodation. Price freehold £1,900, £1,200 on mortgage. Prem. £2,300. Cottage Hosp. and good scope for major surg.
27. PARTNERSHIP.—OXON.—Delightful residential district, near good town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,540, and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 2 years' purchase.
28. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 380. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1½ years' purchase.
29. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
30. SOUTH-WEST OF ENGLAND.—POPULAR COAST TOWN.—A one-third share in an old-established PRACTICE, having good surgical scope. Gross cash receipts average £4,200. Panel of 1,800. Suitable house available on rental. Premium £2,250.

ASSISTANTS REQUIRED.—(1) Sussex. Better-class Practice. Either indoor or outdoor. £300 p.a., all found. Single or married, with prospect Partnership. (2) Dorset. Indoor, £300 p.a. Sport available. NATURALLY RICH IN VITAMIN "D"

DEMINERALISED PASTURES

The nutritional value of a milk is intimately dependent on the diet of the cow. Any deficiencies in the diet are reflected in the quality of the milk.

It is now universally acknowledged that of the various factors of nutrition, mineral salts play the most important role. Lime and phosphate deficiencies, which are widely prevalent in many milk producing countries, result in milks poor in these minerals, and in gradual deterioration of the stock which has to be made good by the constant influx of new blood from the herds of this country.

The importance of ample supplies of these essential mineral salts in a milk used for infant feeding requires no stressing. It is futile for a milk to be rich in Vitamin 'D,' whether naturally so or as a result of additions in the shape of irradiated ergosterol, unless the calcium content is adequate.

Milk used in the preparation of Cow & Gate is produced from the rich pastures of Somerset and Dorset where cattle are healthy and sturdy, and have never displayed those symptoms of mineral deficiency which result in "osteophagia" or wanderings to "salt licks" so often met with overseas.

The improved Cow & Gate Roller process carried out in modern hygienic factories, ensures the retention of the calcium and phosphorus salts of the original milk and preserves the balance of natural vitamins required for their assimilation by the infant. For this reason it is unnecessary to add synthetic Vitamin 'D' to Cow & Gate products.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital is now open for suitable general surgical cases at 17, Park Lane, London, W.1. The fees for a room cost now only two guineas a week, interest in the project having made possible a series of four further reductions since the scheme was started.

The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses, and yet at the same time to avoid any semblance of a charity which would be distasteful to such.

The only condition attaching to the endowment is that any advantages such as they are should be widely advertised, and not in any way limited to any small section of the community. A further promise is made that if, and as, more beds are required they will be provided.

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane.
Telephones: **Grosvenor 2312 & 2313.**

A TYPICAL SCALE OF REDUCED FEES FOR SURGICAL CASES IN THE ANNEXE CLINIC OF THE HAROLD FINK MEMORIAL HOSPITAL AT 17, PARK LANE.

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	**£6 6 0**
Dressings, Theatre Fees, etc.	**1 1 0**
Anaesthetic Fee	**3 3 0**
Surgical Fees for Major Operation (from one-tenth usual charges, according to patient's means)	***(say)* 10 10 0**
(From Twenty guineas inclusive fee)	**£21 0 0**

N.B.—The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant, who may of course be present at the operation, and who, if convenient to himself, will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance.

When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in-Chief (with a view, for example, to a Bismuth Meal, Cystoscopic, X-ray Examination, etc.), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made. (Proportionately reduced nominal fees only charged therefor.)

Telephones: **Grosvenor 2312 & 2313.**

All rooms are of course separate, and hold one patient only, there being no wards.

British Medical Journal.

LEWIS'S PUBLICATIONS

JUST PUBLISHED. Second Edition, with 109 Illustrations. Demy 8vo. 12s. 6d. net; postage 9d.

THE ACTION OF MUSCLES:

Including Muscle Rest and Muscle Re-Education.

By Sir COLIN MACKENZIE, M.D., F.R.C.S., Professor of Comparative Anatomy and Director of the Australian Institute of Anatomy, Canberra.

With 26 Plates (including 6 coloured) and other Illus., 15 Diagrams, and 34 Charts. Demy 8vo. 30s. net; postage 9d.

A TEXTBOOK OF INFECTIOUS DISEASES

Being the Third Edition of Goodall & Washbourn's MANUAL OF INFECTIOUS DISEASES.

Revised and in large part rewritten by E. W. GOODALL, O.B.E., M.D., B.S.Lond., lately Medical Superintendent and Lecturer on Infectious Diseases and Fever Hospital Administration at the North-Western Hospital of the Metropolitan Asylums Board; Vice-President (formerly President) of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, etc.

"Dr. Goodall's long and intimate acquaintance with the infectious diseases makes this volume very acceptable . . . thoroughly up to date and should make a valuable addition to the library of every medical practitioner."—THE LANCET.

With 25 Illustrations, including 17 Plates. 9s. net; postage 6d.

STERILITY IN WOMEN: Diagnosis and Treatment

By SIDNEY FORSDIKE, M.D., B.S.Lond., F.R.C.S.Eng. and Edin., Surgeon to the Hospital for Women, Soho Square, London; Gynæcological Surgeon to the Kensington, Fulham, and Chelsea Hospital; Author of "*The Effects of Radium upon Living Tissues*," etc.

"The monograph shows in every page evidence of rich personal experience, and will well repay the most careful study."—LANCET.

JUST PUBLISHED. Crown 8vo. 5s. net; postage 4d.

THE MORPHINE HABIT

And its Painless Treatment

By G. LAUGHTON SCOTT, M.R.C.S., B.A.Oxon., lately Senior Physician, London Neurological Clinic.

EIGHTH EDITION. With 91 Illustrations in the text and 2 Plates. Demy 8vo. 21s. net; postage 9d.

HYGIENE AND PUBLIC HEALTH

(PARKES AND KENWOOD).

Revised by HENRY R. KENWOOD, C.M.G., M.B., F.R.S.Edin., D.P.H.Lond., Emeritus Professor of Hygiene and Public Health in the University of London, etc.; and HAROLD KERR, O.B.E., M.A.Dunelm, M.D.Edin., D.P.H.Camb., Professor of Hygiene and Public Health in the University of Durham, etc.

". . . the work has been brought up to date . . . and will continue to prove the 'guide, philosopher and friend' of all who wish to learn the principles and practice of preventive medicine."—THE MEDICAL OFFICER.

FIFTH Edition. Revised and Enlarged. With 11 Plates (6 Coloured) and 76 other Illustrations. Demy 8vo. 21s. net; postage 9d.

MIND AND ITS DISORDERS:

A Textbook for Students and Practitioners.

By W. H. B. STODDART, M.D.Lond., F.R.C.P., Physician for Mental Diseases, St. Thomas's Hospital; Lecturer on Mental Diseases, St. Thomas's Hospital Medical School; late Examiner in Psychology and Mental Diseases to the University of London, etc. [*Lewis's Practical Series.*

"Students, practitioners, and specialists will all find much of value in this eminently readable volume."—THE PRACTITIONER.

With 33 Illustrations. Crown 8vo. 7s. 6d. net postage 5d.

CANCER

A Practical *Resume* of the Subject for General Practitioners.

By C. JEANNENEY, Professor in the Faculty of Medicine, Surgeon to the Hospital of Bordeaux, etc. Translated by JOHN GIBSON, M.C., M.A., M.D., Physician to the Victoria Hospital, Burnley, and JOHN H. WATSON, M.B., B.S., F.R.C.S., Surgeon to the Victoria Hospital, Burnley.

"Professor Jeanneney's succinct manual should be studied by every general practitioner."—MEDICAL PRESS.

TENTH Edition. Foolscap 8vo. 6s. 6d. net, postage 4d.

A HANDBOOK OF SANITARY LAW

For the Use of Candidates for Public Health Qualifications.

By B. BURNETT HAM, M.D., M.R.C.S., D.P.H.Camb., Fellow of the Royal Sanitary Institute; Fellow of the Royal Society of Tropical Medicine and Hygiene; Late Commissioner of Public Health for the State of Queensland, Australia, etc.

"It contains a mass of information, and the candidate who masters it need fear no examiner."—THE LANCET.

With 50 Illustrations. Crown 8vo. 5s. net; postage 3d.

BRANCHIAL CYSTS

and other Essays on Surgical Subjects in the Facio-Cervical Region.

By HAMILTON BAILEY, F.R.C.S.Eng., Surgeon, Dudley Road Hospital, Birmingham; late Assistant Surgeon, Surgical Registrar and Tutor, Liverpool Royal Infirmary, etc.

"Of definite practical value . . . the present volume is decidedly opportune."—BRITISH JOURNAL OF SURGERY.

With 186 Illustrations, included in 93 Plates (1 Coloured) and the Text. Demy 8vo. 25s. net; postage 9d.

CHRONIC (Non-Tuberculous) ARTHRITIS

Pathology and Principles of Modern Treatment.

By A. G. TIMBRELL FISHER, M.C., F.R.C.S.Eng., late Hunterian Professor, Royal College of Surgeons of England; Assistant, Surgical Unit, University College Hospital, etc.

"Mr. Timbrell Fisher has established the existence of facts hitherto unknown and has made valuable contributions to our knowledge. His book is to be recommended."—BRITISH MEDICAL JOURNAL.

BY THE SAME AUTHOR.

With 79 Illustrations on 49 Plates and 1 Text-figure. Demy 8vo. 12s. 6d. net, postage 6d.

INTERNAL DERANGEMENTS of the KNEE-JOINT:

Their Pathology and Treatment by Modern Methods.

"An admirable monograph which may be regarded as a type of what a monograph should be."—THE PRACTITIONER.

BY THE SAME AUTHOR.

With 62 Illustrations. Demy 8vo. 9s. net; postage 5d.

TREATMENT BY MANIPULATION

A Practical Handbook for the Practitioner and Student.

"This edition will no doubt be even more welcome to the profession than its predecessor."—THE LANCET.

". . . one is carried away by the admirable presentation of the subject . . . forcible, clear, and concise . . . deserves to be well studied by physician and surgeon alike."—JOURNAL OF BONE AND JOINT SURGERY.

Physiology of the Central Nervous System and Special Senses

(For the use of Students.)

By N. J. VAZIFDAR, L.M. & S., F.C.S., F.C.P.S.,

Assistant Chemical Analyser to Government of Bombay; Fellow of the Indian Chemical Society; Examiner in Physiology and Examiner in Medical Jurisprudence, College of Physicians and Surgeons, Bombay; Examiner in Chemistry and Examiner in Medical Jurisprudence and Mental Diseases in the University of Bombay.

FIFTH EDITION. WITH THIRTY ILLUSTRATIONS.

EXTRACT FROM REVIEWS OF PREVIOUS EDITION.

A careful compilation, Dr. Vazifdar's book is intended to help students through their intermediate examination and it covers the ground adequately.—*British Medical Journal.*

This is an admirable abstract or résumé of a description of the physiology of the Central Nervous System and the Special Senses. The abstract is based upon well-known textbooks of physiology and is accurate and up-to-date in its information. The author may be congratulated on having produced a book of distinct utility to the Indian students. Being a résumé the book is useful to students and practitioners for revision and reference purposes. There are numerous diagrams and tabular statements which help not only in grasping the facts, but in remembering them. The popularity of the book is well deserved.
—*The Indian Medical Gazette.*

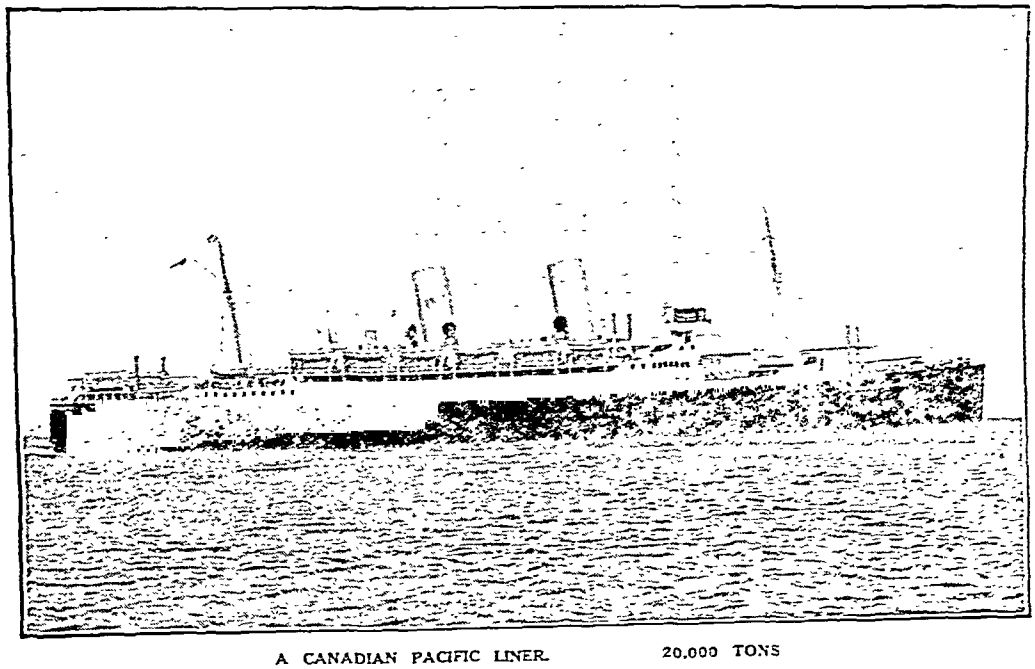
Canada this year

Members of the British Medical Association are specially reminded that this year it has been arranged to hold the Annual Meeting in Winnipeg, Manitoba, Canada.

The British Medical Association and the Canadian Medical Association, in collaboration with the Canadian Pacific Railway and Steamships, have arranged a number of attractive journeys for B.M.A. Officers and Members taking part in the Meeting.

These Official Tours will leave England on AUGUST 8th and AUGUST 15th by

CANADIAN PACIFIC
DUCHESS STEAMSHIPS



"DUCHESS OF BEDFORD" - AUGUST 8th.
"DUCHESS OF YORK" - - AUGUST 15th.

Make this the opportunity of combining business with pleasure. Attend the

98th ANNUAL MEETING

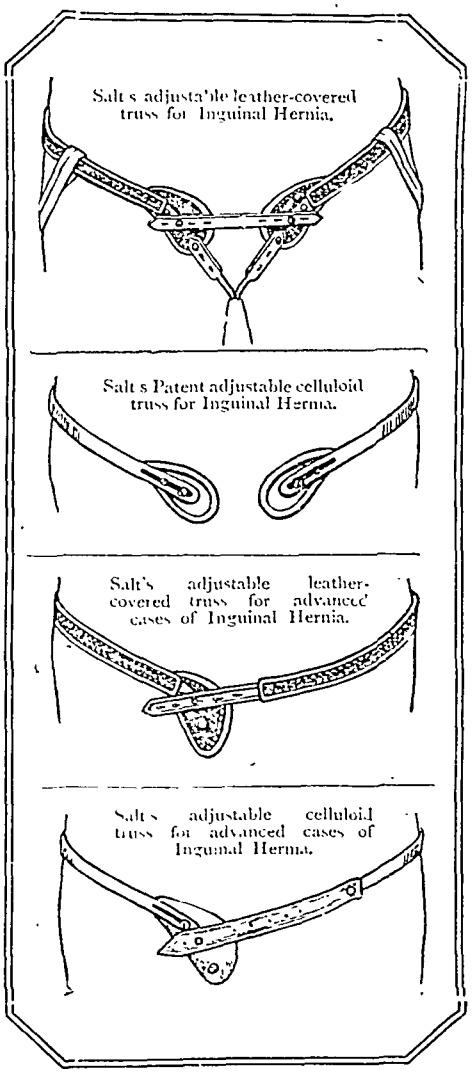
AUGUST 26th to 29th, 1930

have an enjoyable voyage across the Atlantic and, if time permits, extend your stay in the Dominion.

A CANADIAN PACIFIC LINER. 20,000 TONS

All information can be obtained, and Registrations must be made, through the Financial Secretary of the Association at

BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, W.C.1.



SALTAIR SURGICAL SERVICE

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

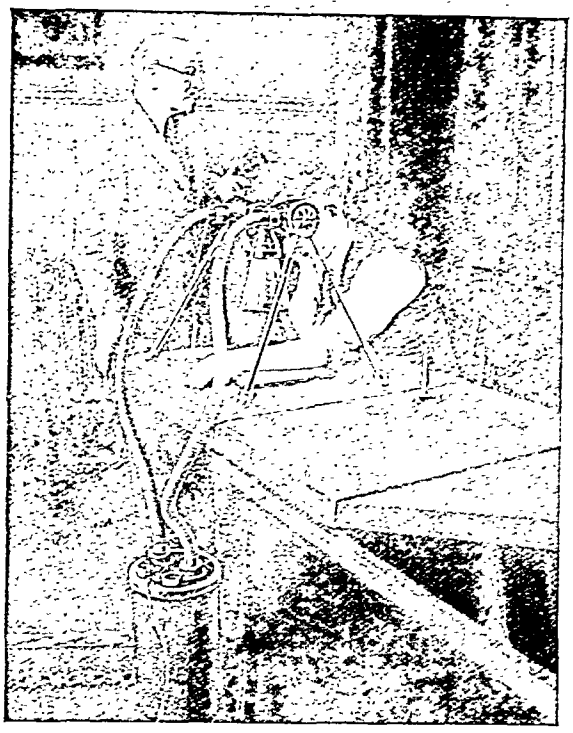
Salt and Son Ltd.

INDIVIDUAL TRUSSES ONLY SUPPLIED.

That part of our Surgical Service relating to the supply of "trusses" is a well-known success.

This is due, in our opinion, to our knowledge in correctly interpreting doctor's instructions and also the fact that every truss we supply is an "*individual*" truss in the true sense.

We keep a stock of several thousands of hand-made springs of different gauges and tempered in varying strengths. In addition, we have pads of many shapes and sizes. From these components we "*build*" the truss and cover it as required.



In all cases our aim is to make an "*individual*" truss for each patient, suitable in fit, quality, and price.

Illustrated price List with measurement forms sent on request.

SALT AND SON LTD.

COPYRIGHT

ESTABLISHED 1793

X-rays are essential to a well-equipped surgery . . .

The doctors who use the "Metalix-Portable"—and there are many—have put behind them the times when their diagnosis was sometimes attended by an element of doubt. They can make X-ray examinations in their own surgery instantly, without trouble, danger, or expense. Should the patient be bed-ridden, the "Metalix-Portable" can be taken to his bedside.

With your consent will we instruct a representative to carry out a demonstration in your own consulting room, when you will be able to witness the amazing ease with which the "Metalix-Portable" is operated and judge for yourself the quality of the radiograms that can be made with it.

FOR INTERNAL TREATMENT OF
GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal-Wood, the oil is bland and remarkably
FREE FROM THE IRRITANT AND NAUSEATING EFFECTS
which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2.

A·K

SANTAL MIDY

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid-base equilibrium of the body.

Samples and Literature on request to Sole Agents:

Safe—useful—portable

Also in exactly similar form
SOLID IODINE

The manifold uses of H_2O_2 are known to all members of the medical profession. 'Peroxtik' is the only solidified form of Peroxide of Hydrogen in existence. Its utility, portability and safety is obvious, and every tube is guaranteed to maintain its original 10-volume strength, for a reasonable period. Medical men interested in H_2O_2, who are desirous of testing 'Peroxtik,' should not fail to write for a free sample tube to ARTHUR H. COX & Co., LTD., 93, Lewes Road, Brighton.

Total extract of the glands of the intestine Biliary Extract-Agar-Agar-Selected lactic ferments

TAXOL

LABORATOIRES REUNIS LOBICA, 46, Avenue des Ternes, PARIS.

ALIMENTARY TOXAEMIAS

PUTREFACTIVE bacteria increase in numbers in the intestine as age advances, They are relatively scanty in the young child, but after middle life are usually present in considerable numbers. Of the micro-organisms concerned, proteolytic anærobes are probably the most important.

In individuals with a normal intestine and free evacuations, they may do little harm, but in those subject to intestinal catarrh, these putrefactive bacteria become more numerous and active, their products are formed in greater quantity, and are more freely absorbed, and the condition of alimentary toxæmia results. The manifestations of this state are very protean, *e.g.*, "rheumatic" conditions, digestive upset, neurasthenia and neuralgias, increased blood pressure and its complications, and many others. The treatment, in the first place, obviously should be *intestinal disinfection*. For this purpose nothing surpasses the use of KEROL CAPSULES. They have solved for years the question of disinfection of the alimentary tract. They definitely reduce the bacterial content of the intestine, as shown by the reduction in B. *coli* by 99% when the capsules are regularly administered for a period of from seven to ten days. We have from time to time published several booklets containing clinical evidence as to their value, and these we will gladly forward, on receipt of a postcard, to any member of the Medical Profession.

IT IS PLEASANTER TO USE

K-Y Jelly is greaseless and does not soil the clothing or irritate the skin. It flows freely, never binds, and can be squeezed out of its tube quickly and conveniently in exactly the quantity required. It is easily removed from hands and instruments by rinsing them in water. Prepared from vegetable substances blended with correctly balanced proportions of boric acid, K-Y Jelly is more "slippery" than petrolatum and never spoils or becomes rancid or poisonous. Physicians and surgeons are invited to write for samples to Dept. B, Johnson & Johnson (Gt. Britain) Ltd., Slough, Bucks, stating name of their local supply house.

* * *

Lubricating Jelly is obtainable from all supply houses and pharmacists throughout the world. Tubes in cartons, 1/3 and large size, 2/6).

The British Drug Houses Ltd. Graham Street, London, N.1

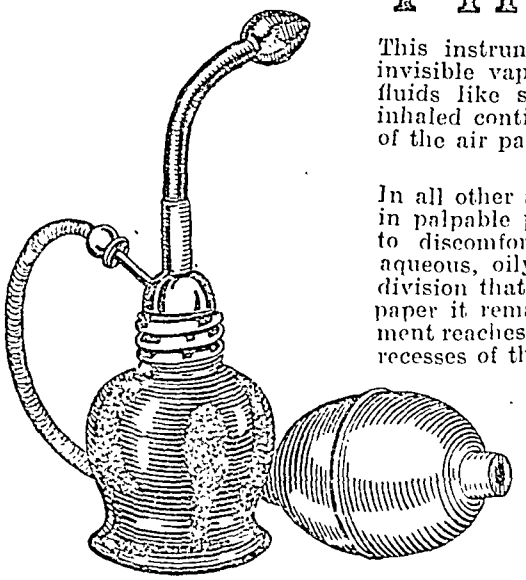
A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.



We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

The Treatment of Pulmonary Affections by Inhalation.

THE AËRISER

This instrument converts liquids into a voluminous but almost invisible vapour, or, in the words of the "LANCET," it "renders fluids like smoke," and thus enables medicated vapours to be inhaled continuously without injury to the delicate mucous lining of the air passages.

In all other sprays, atomisers, inhalers, etc., the spray is given off in palpable particles and cannot be used long without giving rise to discomfort. With the Aëriser, however, solutions, whether aqueous, oily, or balsamic, are given off in such a state of fine division that when the vapour is directed on to a sheet of glass or paper it remains unsoiled: consequently, when inhaled the medicament reaches the whole of the respiratory tract even to the innermost recesses of the lungs without causing the slightest irritation.

BOOTS PRODUCTS

Acriflavine (BOOTS)

One of the most potent of modern antiseptics, physiologically pure and extremely soluble in water. ACRIFLAVINE (BOOTS) kills organisms in a concentration of 1 in 100,000. Its potency is actually increased when brought into contact with serum. Now recognized as the routine preparation for irrigations in the treatment of gonorrhœa. Ideal for suppurating wounds and septic conditions of all kinds.

ACRIFLAVINE (BOOTS) is supplied in 5 gm. and 20 gm. bottles, and in tablets (1.75 gr. and 2,187 gr.).

NEUTRAL-ACRIFLAVINE (BOOTS) is specially prepared for internal use in the form of enteric-coated tablets, and also for hypodermic or intravenous injections.

NEUTRAL-ACRIFLAVINE (BOOTS) is supplied in 5 gm. and 20 gm. bottles; in tablets (1.75 gr.) and in enteric-coated tablets (½ gr.).

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria; gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7.

Works: KING'S LANGLEY, HERTFORDSHIRE. M251

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER Ltd., Manufacturing Chemists,
184, Queen's Gate. London, S.W.7.

When in Doubt—?

"Just as in whist, in the old days, I always led a trump when in doubt, so also when in doubt as to treatment of gastro-intestinal disturbance I have prescribed Dimol for a number of years with the most gratifying results."

————, M.D.

No dicta of disbelief, based on laboratory experiments only, can upset the potency and non-toxicity of Dimol in clinical experience.

By the oral administration of 3 Dimol pulverettes thrice daily all putrefactive organisms and pathogenic streptococci are so reduced in number that rest is given to the poisoned distended gut and recovery established.

Dimol decides decisively doubtful diseases of intestinal origin.

After long and thorough investigation at the Royal Naval College, Greenwich, Dimol pulverettes are now supplied by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

Samples and Literature will be sent on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

Rheumatism a Deficiency Disease?

N.S.D.128.—I have found this preparation remarkably beneficial in every case in which I have tried it. ——, M.B.

R.2.—There is no doubt that my rheumatism is much better, and I feel sure that this improvement is due to Bemax. ——, M.R.C.S., D.P.H.

D.G.2.—My wife began to notice improvement after five weeks. Since then she has put on seven pounds in weight. She is much better generally. ——, M.D.

A few years ago a British Medical Man engaged upon researches into vitamin activity noticed the remarkable effect of a B Vitamin deficient diet upon the incidence of Rheumatoid Arthritis. He was led to the conclusion that the absence of this vitamin was one of the principal predisposing causes of the disease.

The preparation of BEMAX was a direct result of these researches, and since its introduction the evidence of its value for the alleviation and prevention of rheumatic affections has accumulated.

Bemax is a cereal food prepared from the living embryo of selected cereals. It contains a higher percentage of natural Vitamin B than any other known substance, as well as Vitamin A and E and valuable mineral salts. A tablespoonful a day provides all the Vitamin B required to restore a balanced metabolism.

Medical men are invited to send for Laboratory Reports on Bemax and a sample tin for personal trial.

BEMAX

The Most Concentrated Extract of Natural Vitamin B.

THE BEMAX LABORATORIES, 38, DANEMERE STREET, LONDON, S.W.15.

MEDICINAL GLUCOSE B.D.H.

Pure Dextrose

Inability to consume or to assimilate the requisite amount of carbohydrate is the cause of a number of common disorders and of many ill-defined complaints. The remedy for these conditions is found in the administration of glucose—the carbohydrate most readily assimilated.

Medicinal Glucose B.D.H. or, in other words, pure dextrose, is a white crystalline powder of so high a degree of purity that it can be used for intravenous injection as well as for oral administration.

Medicinal Glucose B.D.H. is recommended for use in the nervous excitement and cyclic vomiting of children, in asthma, in the prevention of surgical shock, in sea-sickness and in the various other conditions of deranged metabolism which are associated with acidosis.

Medicinal Glucose B.D.H. is a white powder of exceptional purity; it is supplied in tins of two sizes containing ½-lb. and 1-lb.

In Septic Conditions

ACRIFLAVINE

"B. D." Brand

Acriflavine is an antiseptic of unusually wide application.

Originally employed as a wound dressing, it has now become the antiseptic of choice in the treatment of gonorrhœa; it is of recognised value also in dermatology, in dentistry, in ophthalmic surgery, and in general conditions of sepsis.

Acriflavine "B.D." Brand—the proven British brand—holds its supreme position among other brands of Acriflavine because of its purity and its efficacy in use.

Acriflavine "B.D." Brand is issued in powder form, also in tablets, in solution, in an ointment, in bougies and in suppositories.

Gastritis, Gastric and Duodenal Ulcer

That BiSoDoL is a therapeutically sound preparation will be readily appreciated from its formula.

BiSoDoL is a balanced combination of the Sodium and Magnesium bases with Bismuth Subnitrate, Carica Papaya, Malt Diastase, and Mentha Piperita.

BiSoDoL supplies a convenient and agreeable product for the treatment of gastro-intestinal conditions associated with hyperacidity. It is a valuable preparation for allaying such digestive symptoms as eructations, flatulence, distension and nausea.

BiSoDoL is also giving excellent results in the alkaline treatment of gastritis, and of gastric and duodenal ulcer as well as in the control of cyclic vomiting, and the morning sickness of pregnancy. In the latter the effect of BiSoDol has been especially noteworthy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

BiSoDoL Limited,

PLURIGLANDULAR DISPENSING

The growing and varied needs of the profession in this respect are well catered for in our Organo-therapeutic Dispensary. A complete range of Gland Substances is always in stock and prescriptions can be promptly and accurately dispensed. The following are two of our recognized formulæ.

THYROSEX Co.

Thyroid sicc. ... ... gr. 1/4
Whole ovary sicc. ... gr. 1/2
Whole pituitary sicc. ... gr. 1/10

This represents one average dose and is contained in one Tablet (O.T.M. 520) or in one drachm of the Elixir (O.T.M. 530).

Thyrosex Co. (Evans') is designed for the treatment of the sexual disorders of puberty and for the neuroses and psychoses of menstruation. It is also well worth a trial in mental disorders associated with the menopause, in the treatment of acne at puberty, in skin affections occurring during pregnancy, and in certain cases of obesity, especially in women.

MAMMARY Co.

Mammary sicc. ... ... gr. .1
Whole pituitary sicc. ... gr. 1/2

This represents one average dose and is contained in one Tablet (O.T.M. 590) or in one drachm of the Elixir (O.T.M. 595).

In this formula the antagonism of the mammary gland and the ovary is utilised for the treatment of those conditions arising out of hyperactivity of the ovary. Its use is particularly indicated for older women. Mammary gland substance has been found useful in relieving the symptoms of uterine fibroids, metrorrhagia following functional neuroses associated with hyperovarism, and uterine hæmorrhage generally, especially when administered in conjunction with ergot.

Full particulars of these and other formulæ will be found in our Brochure on "Pluriglandular Function," which may be had on application to—

Evans' Biological Institute, Runcorn.

NATURALLY RICH IN VITAMIN "D"

DEMINERALISED PASTURES

The nutritional value of a milk is intimately dependent on the diet of the cow. Any deficiencies in the diet are reflected in the quality of the milk.

It is now universally acknowledged that of the various factors of nutrition, mineral salts play the most important role. Lime and phosphate deficiencies, which are widely prevalent in many milk producing countries, result in milks poor in these minerals, and in gradual deterioration of the stock which has to be made good by the constant influx of new blood from the herds of this country.

The importance of ample supplies of these essential mineral salts in a milk used for infant feeding requires no stressing. It is futile for a milk to be rich in Vitamin 'D,' whether naturally so or as a result of additions in the shape of irradiated ergosterol, unless the lime and phosphorous content is adequate.

Milk used in the preparation of Cow & Gate is produced from the rich pastures of Somerset and Dorset where cattle are healthy and sturdy, and have never displayed those symptoms of mineral deficiency which result in "osteophagia" or wanderings to "salt licks" so often met with overseas.

The improved Cow & Gate Roller process carried out in modern hygienic factories, ensures the retention of the calcium and phosphorus salts of the original milk and preserves the balance of natural vitamins required for their assimilation by the infant. For this reason it is unnecessary to add synthetic Vitamin 'D' to Cow & Gate products.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

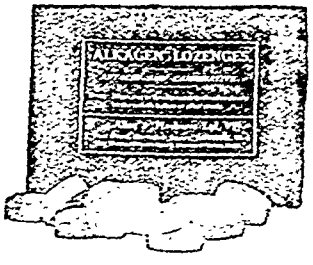
AN EFFECTIVE ANTACID AND CARMINATIVE FOR HYPERACIDITY AND FLATULENCE

'Alkagen'

Trade Mark

An effective Antacid and Carminative for Hyperacidity and Flatulence. It provides a neutralising agent which is easily disintegrated, sufficiently soluble and prompt in effect, whilst unlike preparations of the alkaline carbonates or bicarbonates, it does not cause the evolution of carbon dioxide in the stomach.

'Alkagen' Tablets



'Alkagen' in the form of compressed tablets: one to three may be swallowed with water as required.

In bottles at 1/6, 2/6, 4/6 and 8/6

'Alkagen' Lozenges

'Alkagen' Lozenges present 'Alkagen' in the form of a lozenge possessing an agreeable, mild peppermint flavour. One or two should be sucked slowly as required. They are especially suitable for neutralising acidity of the mouth.

In boxes at 1/3, 2/9 and 5/- per box

Descriptive literature and a clinical trial sample will be sent post free on application.

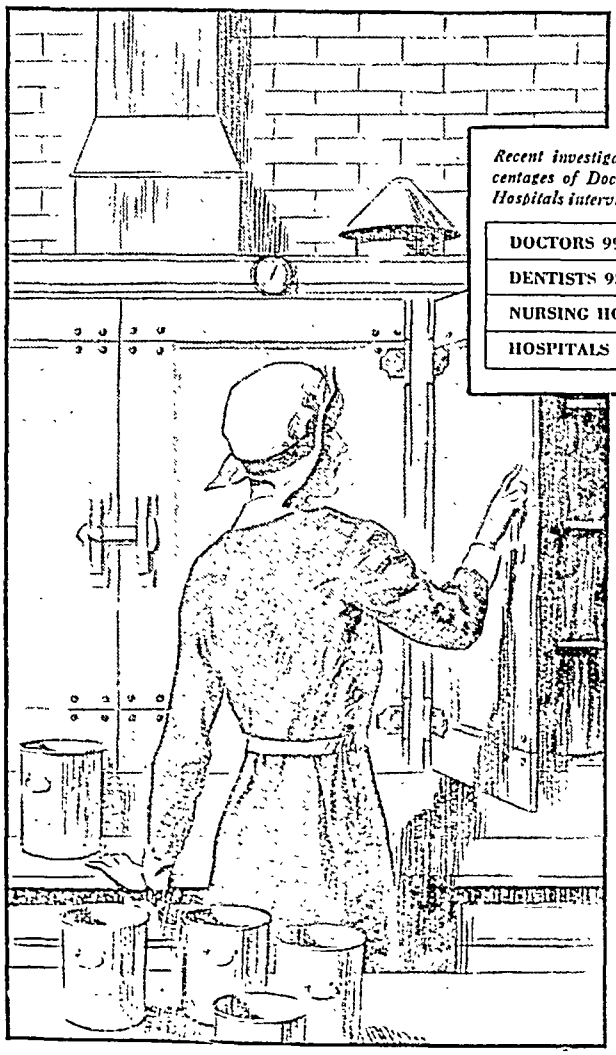
At that critical time when solid food cannot be taken—

THEY STIMULATE THE SYSTEM AND ROUSE THE APPETITE!

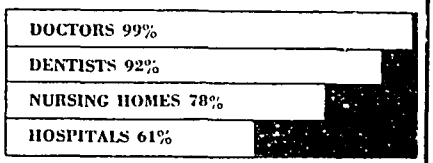
BY APPOINTMENT

Through this wonderful process — exclusive to Brand's — the pure essence of the finest meats is expressed and conserved in its natural form.



TODAY, in cases of serious illness and in convalescence, leading British practitioners find Brand's Essence an ideal restorative. A recent investigation shows that 99 *out of every* 100 doctors interviewed recommend this famous product.

Containing all those valuable elements of meat which excite the gastric secretions, Brand's Essences promote the flow of these secretions and rouse them to the work of digestion instantly.



They are formed entirely of the pure essences of the finest meats, expressed and conserved in their natural state. There is not a particle of harmful colouring, flavouring, or added gelatine in Brand's Essences.

This delicious, palatable jelly can be absorbed rapidly, without the slightest strain on the digestive organs, however delicate their condition.

In acute illness, Brand's Essences stimulate — carry the patient through the most trying periods. And in convalescence, when ordinary food is intolerable, they awaken appetite and make the patient more responsive to solid diet.

Recent investigation shows that the following percentages of Doctors, Dentists, Nursing Homes and Hospitals interviewed recommend Brand's Essences

They are obtainable at chemists and stores throughout the world in small and large-sized tins and glasses. On receipt of a professional card, samples of the Essences will be sent you at once. Write Dept. F3, Brand & Co. Ltd., Mayfair Works, Vauxhall, s.w.8.

PLAN OF A BYZANTINE CHURCH. AN EARLY EXPERIMENT IN A NEW STYLE OF ARCHITECTURE EVOLVED FROM CLASSICAL AND ORIENTAL FORMS.—Outside Constantinople some of the finest and most interesting Byzantine monuments are found in Ravenna, where can be traced the evolution of early types. In the plan of the church here reproduced is seen the oriental influence developed by the Byzantine pioneer architects into a new form. Its characteristic feature is the cupola raised upon a polygonal base. The plan of St. Vitale is original and masterly, especially in the handling of problems of equilibrium. It shows an octagon upon which are raised the stout pillars which support the cupola; these pillars are strengthened and united to each other by eight exedras—or rather seven exedras and a long apse—which help, in addition, to enlarge the central space. Before the west front is built at an oblique angle a narthex or oblong portico which is flanked by two towers. The interior of the church is decorated with great splendour. Its capitals, one of which is here illustrated, are richly and variously sculptured, and its mosaics are amongst the most famous in the world.

RELIEF OF PAIN.

The pain-relieving value of **'VERAMON'** is pronounced and its usefulness covers an extremely wide field of treatment.

In such conditions as

HEADACHE, TOOTHACHE, DYSMENORRHŒA,

it exercises a prompt and lasting analgesic effect, while in the severe pains of

RENAL CALCULUS, OÖPHORITIS,

and even of

INOPERABLE CARCINOMA,

it supersedes, or at least defers, the use of morphine.

A feature of **'VERAMON'** is its safety in therapeutic doses.

Tubes of 10 and 20 tablets (grs. 6).
Bottles of 100, 250, and 500 tablets.

DOSE: 1-2 tablets according to severity of pain.

Clinical sample and literature on request from the following Overseas Depôts:

A British Medical Association Lecture
ON
THE PRESERVATION OF A HEALTHY AND EFFICIENT CIRCULATORY SYSTEM FROM CHILDHOOD TO ADVANCED AGE.*

BY

SIR JAMES BARR, C.B.E., LL.D., M.D., F.R.C.P.,
CONSULTING PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.

THERE is one point which I wish to emphasize at the outset: you cannot have a clear and comprehensive knowledge of diseases of the respiratory and circulatory systems without a good conception of physics. Time will not permit me to deal with these matters here except on broad lines, but there are several of my papers where you will find the physics in full detail.

I am more concerned with the preservation and efficiency of health than the mere prolongation of life: a sound mind in a sound body—the former can scarcely exist without the latter. When I travel outside the beaten paths of traditional medicine I do not wish you to accept anything which I say until you have proved it for yourselves. The only knowledge worth anything is that which you acquire for yourselves and make your own. Prove all things, hold fast to that which is good. Accept facts and not mere opinions, no matter by whom uttered.

The objects of the circulation are to convey oxygen and nutritive material to the tissues, and remove carbonic acid and other waste products therefrom. I look upon the circulatory system as one unit, but although we have numerous books on diseases of the heart, it is only of recent years that much attention has been paid to the distributing tubes. When in 1906 I gave the address at the meeting of the British Medical Association in Toronto on the circulation viewed from the periphery[1] it was generally considered that I had opened up a new vista. On many occasions I have dealt with the parts played by the arteries, arterioles, capillaries, and veins.[2] The old trite saying of Cazalis, that a man is as old as his arteries, should be extended—that his arteries are as old and efficient or inefficient as his endocrine glands. The part which these organs play in the maintenance of an efficient circulation is not yet fully recognized. The preventive side of medicine apart from that dealing with infectious diseases, which I believe is going to be the medicine of the future, is only slowly developing. The reason for this is that prevention does not pay the individual practitioner, and the public do not believe in paying for what may never happen. Moreover, it is not always an economic proposition: when a public health officer tells me that in his particular city he has saved so many thousands lives, and actually has the temerity to put a money value on his work, I retort that I would like him to trot them out, and let me see whether they were worth saving, and how long the saving process is likely to last. I believe that every person dying under the age of 20 is an economic failure. Nature weeds out the unfit, and enormous sums of money are spent yearly in thwarting Nature, but in the long run progress must be established and Nature gets her way. R. J. Ewart recorded in the *Eugenics Review* how a few wet summers had enormously reduced the death rate from infantile diarrhœa, but an epidemic of measles came along and wiped out all the inefficient lives that had been saved. War is dysgenic, and in the late great war millions of the fittest of the fit were killed. While our A 1 men were sacrificing life and limb the weaklings at home were propagating the race, but Nature was not going to be thwarted all the time; she came along with a world-wide epidemic of influenza and wiped out more of the weaklings than the numbers of the fit killed in the war. If you want an A 1 race you must breed it; there is no other way. You must apply genetics to the human race just as you do to the lower creation. We want children of choice, not of chance, which is the usual haphazard method in the present day. Those who cannot produce healthy children should leave the job to those who can.

There is no part of the animal economy more under hereditary influences than the circulatory system. We get our health, physique, intellectual capacity, and longevity, in fact, the harmonious working of our endocrine system, from our progenitors. I know that there are many of our profession so imbued with Lamarckian ideas that they will tell us that all children are born healthy, that their potentiality for life is equal, that their bad health depends on the environment. Such doctrines are scarcely worth refuting, as there is no such thing as equality in Nature, not even in the same family. The Mendelian laws should be widely studied and carried out. We should take lessons from horticulturists and animal breeders. The nation that produces the finest and best race is sure to win in the long run. Of course, we do not wish to raise a race of hot-house plants; every progressive race must take risks—the safety first principle never made any nation.

When we get children with healthy circulatory systems it will be necessary that we should know how to keep them not merely healthy but efficient to advanced age. Of course, the circulation of a clerk might be as healthy as that of a navvy, but it would not be as efficient, though it might wear longer. It is unfortunate that we measure the length of our existence by the number of revolutions we have had round the sun rather than by the work which we have accomplished. Before Einstein appeared on the scene it might have been argued, and was successfully argued by many ancient philosophers, that there is no such thing as time; certainly so far as our senses are concerned it is a physical nonentity. A revolution of the earth on its axis we arbitrarily divide into twenty-four parts, which we call hours, and if we are at the Equator we are being whirled round at the rate of 1,000 miles an hour without knowing it. Our ambit round the sun we divide into 365¼ days, and during this excursion we travel at least 68,000 miles an hour. The question, in my opinion, is not how many of these excursions we have had, but what have we been doing? If we be merely parasites the fewer revolutions the better for the nation. What troubles me is that many of our best and most worthy citizens after they have had sixty excursions suffer from a failing circulatory apparatus and die in the most useful period of their lives. They must be taught how to lessen this wasteful mortality, and preserve their utility to a more advanced age.

Many medical men talk very glibly of inductive philosophy, without any clear apprehension of what they mean except that they patronizingly mention Bacon as their guiding star. Bacon, in his description of his method of physical inquiry, lays down the principle by which it is to be guided, but, as Edward Caird pointed out, he exhibits no idea of connecting that method, or those principles, with self-consciousness. He usually speaks as if facts were given through the senses without any aid from reason. When physicians and surgeons speak of their experiences and trot out their thousand cases they fail to see that the mere accumulation of statistics without a guiding principle is useless; a single negative may upset a year's work. Unfortunately, the negatives are too often slipped into another category, or buried, and you hear no more about them. If we are to arrive at any sound conclusion, either by deduction or induction, the critical faculty of reason must be employed; even of our own existence we must be self-conscious. As Descartes said, *Cogito, ergo sum.*

Einstein now seems inclined to join up the electromagnetic and gravitation fields. I think in medicine we should pay a little more attention to the electro-magnetic field than we do. Supposing one stands on the crown of his head, he might not materially alter his position in the magnetic field, but he certainly would in the gravitation field. This is not a practice which I recommend except for experimental purposes. Some young men with good healthy pliant blood vessels can do so with impunity, without any risk of injuring a single cerebral capillary. We must not think that thin-walled capillaries are subjected to the brunt of the ordinary blood pressure with the addition of the weight of a column of blood five or six feet in height. Once the body is inverted the carotid

* Delivered at a meeting of the Border Counties Branch of the British Medical Association, Carlisle, February 20th, 1930.

arteries contract to a half or less of their former dimensions. Then not only is the blood supply diminished, but the increased lateral pressure in the arteries enormously increases the velocity in the arterioles, capillaries, and veins. In these small vessels the velocity and lateral pressure stand in an inverse ratio to one another, so the lateral pressure in the capillaries may be actually diminished. The question of pressure and velocity in all the capillaries of the body was fully discussed in my Toronto address.[1] In my experiments I was the first to discover that the venous blood runs more quickly up the hill than it does down it. This is a claim which no one has ever disputed. The fact is explained when it is recognized that the velocity in the veins depends on the pressure in the arteries.

The principal cause of disease of the heart in early life is acute rheumatism, and therefore if we could get rid of rheumatic fever we would materially lessen the incidence of heart disease. With this object in view an influential committee was appointed by the British Medical Association. It has been at work about three years, and has discovered that 60 per cent. of cases of juvenile rheumatism occur in damp houses; they therefore jump to the conclusion that damp houses are the cause of rheumatism. Architects have been called in, so the prevention of rheumatism is going to be a very expensive business, like most health work undertaken by clinicians. There is nothing said about the 40 per cent. who presumably live in dry houses; otherwise, on any pretext, they would have been used to swell the 60 per cent. There is no mention of the little street urchin who is badly housed, badly shod, badly clothed, badly fed, and exposed to all kinds of weather, but is not particularly prone to rheumatic fever. Too many of our specialists pay no attention to Newton's dictum, if they ever knew it, that we are to admit no more causes of natural phenomena than such as are both true and sufficient to explain their appearance.

Very many years have elapsed since I pointed out that large numbers of children under the age of puberty suffer from defective action of the thyroid gland. Consequently, in Nature's imperfect attempt to remedy the defect, we get increased growth of the lymphoid tissue, adenoids, large tonsils, and subsequent infectious diseases such as rheumatic fever. In these cases there is a defective supply of iodine with lessened calcium metabolism, and an accumulation of lime salts in the tissues. I recommend that a large lump of iodine (or its tincture) be placed in the dormitory in an open vessel near the window, so that the air entering the room may take up a fair amount. The benefit derived at many seaside resorts is partly due to the iodine in the atmosphere. In many cases this is not sufficient, and the medical attendant should exercise his educated judgement as to the amount of iodine and thyroid that should be prescribed in individual cases to prevent the onset of these diseases. Iodine is the natural stimulant to the thyroid gland, and as a rule it is best to make the thyroid do its own work, though in some cases the addition of thyroid may be necessary. The amount necessary for prevention is usually not great, and we must be careful not to overstep the mark, as I have known exophthalmic goitre to be produced by excessive doses of iodine.

Rheumatic fever is supposed to be due to some streptococcus introduced chiefly by the tonsils. Throat specialists have intervened and say the tonsils must be enucleated, so "the latest thing out" is the tonsils. The tonsils often act as a barrier to the entrance of septic organisms to the chest. The enucleation not only removes the filter-bed to the entrance by the lymphatics, but blood vessels are opened up so that infection can get directly into the circulation.

Acute rheumatism occurs more frequently in the children of the artisan class than among the very poor; among these who have had a liberal supply of milk, and have an excessive amount of lime in their fibrous tissues. In rheumatic fever milk should be cut out of the diet, and there should be substituted meat juices, soup, raisin tea or glucose, potassium and sodium salts, and, of course, salicylates. In order to prevent the heart becoming involved the blood pressure should be kept very low. It is always possible to tell when the heart is becoming infected, several days before there is any murmur, by a long dull first sound, and a perceptible delay in the transmission of the pulse wave to the wrist. In addition to the myocardium, the chief valves to become involved are the mitral and aortic. The lesion in the mitral valve[2] arises in the auricular surface about a quarter of an inch from the edge where the cusps come into violent collision, and in the aortic valves in the ventricular surface, where the cusps are driven into forcible apposition by the recoil of the aorta.

Pericarditis is also of frequent occurrence, and when there is excess of lime we get a thick honeycomb effusion which may eventually be absorbed, but when the effusion is more gelatinous and corpuscular adhesions readily take place. The way to prevent the mischief is to keep the blood pressure low, lessen the lime supply, give salicylates with a liberal supply of sodium and potassium citrates or bicarbonates, iodine or the iodides. When the acute stage is over mild exercise is desirable. Absolute rest is the modern treatment, but fortunately it is impossible to make a child a fixture. Avoid heart tonics such as digitalis—irreparable mischief is often caused thereby.

In the *Edinburgh Medical Journal*, December, 1876, I wrote an article on the effects of overwork on the heart and aorta. At that time the British workmen worked, nowadays they play, so that any stress on the heart is usually brought on in the playfields; but as any strain thus incurred is intermittent its effects soon pass away. We hear a good deal about "industrial fatigue," and some men seem to be making a living out of it, but I have not come across anything of the kind for at least a quarter of a century. If excessive strain be too frequently produced, no matter how caused, it tends to dilatation and hypertrophy of the heart, with damage to the aorta and other systemic arteries.

German beer-drinkers used to work hard and drink hard. The low alcoholic strength was sufficient to keep up a constant vasomotor paresis, and thus increase the blood vascular cavity, which was always replete; the quantities thrown out at each beat were large, the systemic blood pressure was always high, with a great disparity between it and the diastolic, so that in addition to the lateral there was also longitudinal strain in the aorta and other large arteries. This led to proliferation of the star-shaped corpuscles in the subendothelial layer of the intima of the large elastic arteries, with subsequent fatty and atheromatous degeneration. In the muscular arteries the degeneration takes place in the media. This leads to loss of elasticity, which occurs most readily when the vessels are constantly on the stretch. The free calcium ions in the blood are deposited in the atheromatous patches as calcium soaps, and afterwards the fatty acids are replaced by phosphoric and carbonic acids. We thus get calcareous plates, which may strengthen the affected parts, but still further reduce the elasticity.

The blood pressure in the arteries is merely a part, though a very important part, of the energy imparted to the blood by the contraction of the ventricles. The energy of the blood in any part of the circuit is a compound of potential and kinetic energy, of lateral pressure and velocity, and the greater the velocity in any part the less the lateral pressure in that particular part. The same considerations apply to the pulmonic circuit, except that the energy is, as a rule, not more than a third of that of the systemic system. There is an important difference as to how the energy of the right ventricle is expressed in comparison with the left. I have calculated that while the pressure in the pulmonic artery is not a third, the velocity is at least three-fourths of that in the aorta. Unlike the vena cava, the pressure in the pulmonic veins is practically always positive, so that the blood enters the left side of the heart under pressure, while it is usually sucked in, or rather driven in, by the atmospheric pressure to the right side. There is a gradual fall in the pressure gradient from the right ventricle to the left auricle, and, as the vasomotor nerve supply to the pulmonary vessels is very limited, there does not seem to be much resistance to the circulation either in the arterioles or capillaries. The blood pressure is considerably raised in the pulmonic circuit in cases of mitral stenosis, and it is in this disease that degenerative changes chiefly take place, and are as

pronounced in the pulmonic veins as in the pulmonic arteries.

A certain degree of blood pressure is essential to the maintenance of life, but the variation has a very wide range to meet the ever-varying demands of the system. What is normal blood pressure either for the individual or the species has never been, and never can be, determined, because the pressure must vary according to the calls of the organs for more or less oxygenated blood. Without a certain diastolic pressure man could not assume and maintain the erect posture.

The primary cause of arterial blood pressure, high or low, depends on the force of the ventricular contractions and the amount of blood thrown into the circulation at each stroke—two variables within fairly wide limits. According to some physiologists the limits of the output are very wide—say, two to fourteen gallons of blood passing through the two ventricles in a minute. This would be all very well for a bullock, but not for human beings. I would advise the output be kept well below this physiological maximum. The greatest toper could not pass nine gallons of beer into his stomach in a day, and, after absorption, that would keep the pump very active, but, I think, scarcely up to fourteen gallons a minute. The pressure also depends on the height of the blood column; hence, in the erect posture, the pressure on the tibial artery is much greater than in the radial raised above the head. It is therefore customary and advisable to take the arterial pressure at the level of the heart. In the healthy adult who is not subjected to much physical stress the systolic arterial pressure may range, say, from 100 to 150 mm. of mercury, while below 100 might be put down as subnormal, and over 150 as supernormal or hyperpiesis. While the heart starts the circulation the maintenance of the pressure largely depends on the resistance to the outflow through the arterioles and the capillaries. A healthy heart has a wonderfully adaptive capacity, so that its reserve force can be called upon at any time to do five or six times as much work as is required of it in ordinary quiet life. It is a self-regulating and self-repairing force pump, so that if there were less tinkering with it the gear would last much longer.

The greater the resistance or amount of work to be done the greater the force of the cardiac contraction, and the higher the lateral pressure within the arteries. If the load be too great the heart may not be able to cope with the work, and we get cardiac failure with consequent abatement of the resistance, so that the heart again may be able to adapt itself to the lessened work. A long-continued high pressure leads to hypertrophy of the heart with increase in the thickness of its walls, and perhaps in the capacity of its cavities, especially when there is a demand for an increased supply of blood; these conditions in turn maintain the arterial pressure at a high level.

As the blood leaves the heart its energy is largely kinetic, and therefore during the systolic period there must be very little lateral pressure at the root of the aorta; but if that vessel be healthy and elastic the largest portion of this energy is rapidly stored up in the walls as potential, which is paid out during the diastole of the heart, and then the blood is compressed with a force nearly equal to that which it transmitted, and this force is equally applied to all parts of the aorta, including its commencement. Thus the blood is driven through the coronary arteries when they are relaxed.

At the opening of the semilunar valves the blood has acquired its velocity head, and then the actual velocity depends on the energy or effective head *minus* the resistance to the outflow. In a large smooth-walled vessel the friction and viscosity of the blood are negligible quantities, but both come into play in the arterioles and capillaries; and the mass of blood is an impediment to its onward movement.

The greater the elasticity of the aorta, the greater the conservation of energy, and hence the pressure and the velocity become more or less uniform during the whole dia-tolic period. The velocity between any two points depends, not on the pressure, but on the difference in the pressures—the pressure gradient. The most perfect circulation is the one with a relatively small difference between the systolic and diastolic pressures, a moderately low systolic and a relatively high diastolic pressure in all the arteries. The systole of the ventricles gives out the energy during the third of a cardiac cycle, and the perfection of the circulation depends on the disposal of that energy not only in the time it is given out, but also in the intervals between the systoles. The diastolic pressure should be more than sufficient to overcome all the resistance, otherwise the blood in the main arteries would come to a standstill towards the end of the diastole. We can therefore look upon the difference between the systolic and diastolic pressures as that part of the energy which is not stored up in the walls of the arteries, and which is used in producing velocity. I think when this difference ordinarily exceeds 40 mm. of mercury there is something wrong with the elasticity of the aorta. This difference between the systolic and diastolic or mean pressure is nowadays called the pulse pressure. I know that the majority of heart specialists look upon a high pulse pressure as evidence of a very efficient circulation, but I think that such an opinion evinces gross ignorance of the physics of the circulation.

A pressure gradient of 5 mm. of mercury in a smooth-walled vein without any resistance gives a velocity of 1,120 mm. of blood in a second, but in an artery, in order to get this velocity, a fall in the pressure gradient from 150 to 100 mm. of mercury is required. With a pressure of 150 mm. and a resistance of 120 mm. of mercury you get a velocity of 640 mm. in the second. This is the kind of circulation that would suit a Methuselah, but it is not often realized.

The estimation of arterial blood pressure with one of the numerous instruments on the market is a very simple matter; hence such instruments are in very common use, and many patients think they have not been properly examined unless their blood pressure has been taken, while, if they are able to display an electro-cardiogram they think their money has been well spent. Such random observations are of very little value; it is not the instrument, but the man behind the instrument, that makes or mars the observation.

We must now consider how the arterial pressure is increased, maintained, and regulated by the resistance to the outflow. The first line of resistance is in the arterioles, which are small muscular vessels well supplied with vaso-motor nerves, and consequently readily contract on any stimulus; the resistance in the arterioles is directly as their length and inversely as the square of their diameter. Here sections, or the fourth power of their cross-friction and viscosity come into play, but not to the same extent as in the capillaries. The arterioles of the splanchnic area, of the skin, and to a less extent of the muscles, are the great regulators of arterial pressure. Often their action is reciprocal; when one set is contracted the other are dilated. The arterioles of the muscles dilate after exercise; hence after a strenuous sprint one may have violent palpitation owing to the great fall in the pressure gradient.

The principal secretory organs which stimulate the vaso-motor nerves are the adrenals and the pituitary. The thyroid, through the sympathetic, stimulates the heart's action, but it lessens the viscosity and the resistance. Both the adrenals and the pituitary, besides their specific effects, raise the blood pressure and lower carbohydrate tolerance. There are numerous pressor agents which act through the vagus or sympathetic nerves, such as digitalis squills, caffeine, strychnine, and many toxins. On the other hand, practically all the bacterial diseases lower the pressure. Hard mental work, and the stimulating effect of cold acting through the sympathetic, contract the arterioles, raise the arterial blood pressure, and increase the urinary flow.

The contraction of the arterioles of large tracts raises the general arterial blood pressure, but when those of small areas only are affected merely local effects ensue. Take a cold hand: there may be a difference of 50 mm. of mercury between the lateral pressure in the radial and in a digital artery, but when the arterioles are dilated there is a much less abrupt fall in the pressure gradient. Frequent contractions and dilatations of these vessels are

sufficient to give rise to tortuous and atheromatous radials, while the central arteries may be quite healthy. It is entirely due to the intervention of the arterioles that the capillaries are protected from the full hydrostatic effects of the blood when the body is in the erect posture.

When the limbs are dependent the potential increases, and if the arterioles be dilated from any cause the pressure in these little vessels and in the capillaries is much augmented, so that petechial haemorrhages may readily occur; but, on the other hand, if the arterioles be contracted the potential is largely converted into kinetic energy in the arterioles and capillaries.

The marvellous regulative mechanism of the vasomotor system enables the blood to be drawn from the high-pressure main—the aorta and its principle branches—to the organs or systems that immediately require it. Witness the great supply to the extremities during exercise, and to the abdominal viscera during digestion. Increase of pressure within a healthy artery improves its tone and raises its coefficient of elasticity. Owing to these facts, as well as to the intervention of the vasomotor nerves, the arteries of the lower extremities contract when they are dependent and dilate when they are raised.

The second line of resistance is in the capillaries, and here it is a compound of potential, friction, and viscosity. The larger the capillary bed the less the resistance. Perhaps not more than a third of the capillaries of the body are full at any time, but when there is great vascularity owing to dilated arterioles the inertia of the mass of blood is an impediment to its onward motion, and in the web of the frog's foot a to-and-fro movement can be seen. In these little tubes there is an enormous amount of friction of the corpuscles against one another and the walls. The resistance is, as in the arterioles, directly as the length of the tubes, etc., and here the viscosity is an important element. The extra-capillary pressure is about one-fourth of the capillary pressure from which it is derived, and is a factor in carrying on the lymph circulation.

Calcium Salts.

Lime salts play a very important role in the animal economy. Without free calcium ions life as we know it would be scarcely possible in the animal and vegetable worlds. Fortunately calcium is very widely distributed over the face of the globe, but mostly as dead inert matter, which, however, can be readily converted into soluble active forms. When I began my work with calcium in the early eighties practically the only soluble salt was the chloride, and most of my experiments were carried on with it. I think very highly of it still, though chemists have placed many more palatable forms on the market.

When, in 1910, I gave my address on the use and abuse of lime salts in health and disease,[4] I naturally referred in very eulogistic terms to Sydney Ringer's epoch-making work. To appreciate Ringer's work properly one should read it carefully, and then, by way of contrast, peruse a discussion at the Edinburgh meeting of the British Medical Association on the therapeutic uses of the calcium salts.[5] If you have the patience to wade through this discussion, then by way of a tonic I would commend to your attention a discussion at the Liverpool meeting in 1912, "On the role of the calcium salts as therapeutic agents."[6]

The lime salts are as a rule badly absorbed, and it is not what is taken into the stomach, but what is absorbed, that works good or evil. Benjamin Moore was the first to point out that calcium is absorbed by the intestinal mucosa as a calcium soap, and when it passes in by the lacteals the calcium ions are set free to play their important role in the animal economy. The stearin and palmitin form insoluble calcium soaps, which pass out by the rectum. We are now told that vitamin D increases the absorption, but we are not told the composition of vitamin D, nor what chemical combination it forms with lime. It is easy to know all that is known about vitamins, and if one acknowledges that he does not know what is not known, his patients may think him very ignorant and much behind the times. Vitamins can be bought by the ton at a very substantial price, yet no chemist, nor even a biochemist, has been able to discover their chemical composition; the nearest approach is that when some of the sterol compounds, such as ergosterol, are exposed to the mercury vapour lamp they become charged with vitamin D, and you must be careful not to overcharge lest the stuff become poisonous. It may thus turn out that vitamins are vibrations in the ether of definite wave-lengths, and a biophysicist may eventually be able to measure the wave-length and determine the dosage.

One of the earliest signs of pneumonia is the disappearance of lime from the urine; it is discharged from the blood with the fibrinous exudate into the alveoli. It is a bad omen when there is a deficiency of calcium in the blood with prune-juice expectoration. All these examinations are within "the competency of any ordinary general practitioner," and should be made within twenty-four hours of the onset of the attack. One should not wait six weeks and get a biochemist to make the discovery.

When in 1907 Blair Bell introduced his method of examining the blood for calcium, many of us examined the blood in all kinds of diseases for the lime salts. I quickly came to the conclusion that his method revealed the free calcium ions and not the fixed lime. In one gentleman aged 74 there was a large amount of fixed lime in his arteries, yet by Blair Bell's method his blood only gave an index of 0.5, or half the normal amount. I put him on a lime-free diet and gave him decalcifying agents freely, such as lemon squash and phosphoric acid. In a short time the calcium index had risen to 1.3. Blair Bell has now come to the same conclusion. I found that the lime salts increase the viscosity of the blood and lessen the velocity of the capillary circulation.

My conclusions are that the fixed lime, or that which is linked on to the molecules of albumin, increases the viscosity, while the free calcium ions in association with the suprarenal and pituitary secretions increase the tone and contraction of the arteries and arterioles, raise the blood pressure, and improve the force and efficiency of the cardiac contraction. In this latter effect the ions of potassium and sodium play an important part. The viscosity is augmented by an increase in the number of corpuscles, by cold, and by carbonic acid. The adrenaline and probably pituitary secretions lead to the retention of lime salts in the blood and tissues, while the thyroid and ovaries increase calcium metabolism, diminish the free and fixed lime in the blood, and thus lessen the viscosity; the parathyroids also increase calcium metabolism, but this is anabolic, while the action of the thyroid and ovaries is katabolic. Although we cannot show with the sphygmometer that a dose of calcium—except intravenously—materially raises the blood pressure, we have the direct evidence that decalcifying agents quickly lessen the viscosity and pressure. These agents do not always lessen the free calcium because they take up a good deal of the loosely fixed lime in the blood vessels and other tissues. Under the free use of phosphoric acid I have seen the free calcium ions increase, while coarse valvular murmurs abated and in some cases disappeared. The blood is the agent for conveying the calcium to the tissues, and from them, when it has served its purpose, to the excretory organs. The lime salts are very apt to get deposited in any part of the body which is not properly functioning. I have seen calcification in the costal cartilages of a man aged 27, produced under the care of an orthopaedic surgeon by long fixation of the chest with a spinal support. Emphysema leads to calcification of the costal cartilages, and, on the other hand, a fixed rigid chest may be the precursor of emphysema, hence the great value of mountain climbing in maintaining a good vital capacity.

Arterio-sclerosis.

However high blood pressure is brought about, it eventually leads to degenerative changes in the coats of the vessels. As the degenerative changes proceed the arteries —especially the aorta—lose their elasticity, consequently the energy imparted by the heart to the blood is not properly stored up, there is a great fall in the pressure gradient between the systolic and diastolic pressures, which leads to longitudinal straining of the arteries, the arch of the aorta gets dilated, and the muscular arteries become tortuous. The best way to prevent and lessen these degenerative changes is to maintain a low systolic and a

relatively high diastolic pressure. We may not be able to regulate the secretions of the adrenals and pituitary, but we certainly can control the high pressure effects which they produce. We can stimulate the thyroid with iodine, also supply thyroid substance, and so increase calcium metabolism.

If the degenerative changes in the aorta have not proceeded too far—and this is most readily measured by the difference between the systolic and diastolic pressures—it is really wonderful what the free and long-continued use of decalcifying agents can accomplish. I have seen aortas which were so much dilated that they could be easily felt in the suprasternal notch, and the elasticity greatly impaired, as indicated by the *loud*, clear, clanging second sound, diminish in size and the second sound become quite normal. I have seen coarse, rough valvular murmurs and cardiac intermissions permanently disappear. Healthy exercise increases calcium metabolism and lowers blood pressure, and for good health a considerable amount of exercise is absolutely essential.

Women are not so liable to arterio-sclerosis as men because their foot-ton output is not so great; they eat less, are more temperate in all things, and, as Blair Bell has shown, they get rid of a good deal of calcium at each menstrual period. When it does occur in women, apart from kidney disease, it chiefly arises in those who have borne large families and in those liable to emotional disturbances; emotion acts like suddenly turning a stopcock in a water-pipe connected with the main; it sets up waves of pressure, the chief stress of which is thrown on the aorta.

In Stokes-Adams disease the contraction of the left ventricle, although very infrequent, is powerful and fairly regular; the systolic arterial blood pressure is high and the diastolic low; there may be two or three ineffective contractions of the right ventricle between the powerful systoles of the left. In these cases you should try to increase the irritability of the cardiac muscle, lessen the remainder contraction of the ventricles, hasten ventricular diastole, and increase intracardiac pressure. To lessen the remainder contraction and hasten diastole active potassium ions are necessary, while the sodium salts should be diminished. For the maintenance of efficient cardiac contraction free calcium ions are essential. Since all agents which increase calcium metabolism do good I have found a useful combination of calcium iodide, potassium chloride, and tincture of iodine, supplemented with thyroid. There is plenty of fixed lime in the system, so what is wanted is not an additional supply but some agent to set the ions free.

I do not pay much attention to the imaginary function of the sino-auricular node as the pace-maker, nor to the stimulus which it is said to generate. This stimulus, if such exists, must be a vitamin, since it has never been isolated nor its composition determined. In very many people after the age of 50 the function of the thyroid begins to wane and the pulse becomes infrequent. I think most people with a slow infrequent pulse will find a great advantage from cutting down the lime salts, and taking a small daily dose of iodine and thyroid.

If we find a person in a dead faint we should not wait for the pace-maker to start the heart, but raise his lower extremities so as to increase the intracardiac pressure in the right auricle and ventricle. This is the best cardiac stimulant, and as the right side of the heart is more irritable than the left, it starts contraction, raises the intrapulmonary pressure which drives the blood into the left auricle. The rhythmic cardiac contraction depends on the difference in electrical potential between the ions within and without the muscle cells; more attention, therefore, should be paid to electrolytes than to an imaginary stimulus which has never been traced outside the brains of cardiologists.

As a matter of routine, in my examinations of the urine I always precipitate the lime as an oxalate. This helps me to estimate not only the activity of the kidneys but also the calcium content of the blood. In all these examinations the condition of the kidneys and the specific gravity of the urine must be taken into account.

In 1903 I was waiting in one of the operation theatres of the Liverpool Royal Infirmary to see an operation on a patient of mine. I heard a noise in the anæsthetic room, passed in, and found the anæsthetist and a nurse busily engaged in performing artificial respiration. I was informed that the patient had ceased breathing. I said that judging from his pulse and colour there could not be much the matter; that if they stopped the artificial respiration and threw a towel over the patient's mouth so as to allow CO_2 to accumulate in the alveoli he would soon start breathing. The anæsthetist mentioned that he had seen this occur in several cases when the ether had been administered by the open method.

When apnœa is established from excess of oxygen and deficient carbonic acid—which is the natural stimulant to the respiratory centre—the worst method of treatment is arterial respiration. We often see reports of inquests where artificial respiration was carried on for hours. The medical attendants get great praise for their perseverance, whereas it would be more correct to say that they deprived the patient of any chance of recovery. It is doubtful if anyone could stand two hours of artificial respiration and survive. In many diseases the free administration of oxygen establishes a partial apnœa, but we must not think that because the patient appears more comfortable we have increased his chances of recovery; on the contrary, we have deprived the heart of the assistance of the respiratory pump. The old closed ether inhaler might half-suffocate the patient, but it never induced a fatal apnœa.

Before prescribing a cylinder of oxygen one should carefully weigh the pros and cons. If one feels certain that it is going to do any good, then let him prescribe it, but it should not be ordered because it is the popular thing to do, or merely on the erroneous idea that it can do no harm. There is much more oxygen in the atmosphere than the blood can under any circumstances appropriate, but the atmosphere ought to be pure and fresh, not pre-breathed. An excellent respiratory stimulant is to play with a fan a stream of cold air on the patient's face. Before we had electric fans I used a foot-bellows.

Auricular Fibrillation.

This is a very common precursor of death, and when the fibrillation extends to the ventricles life can be measured by seconds.

There was a very interesting case of hemisystole in a woman, aged 41, admitted under my care to the Liverpool Royal Infirmary on August 6th, 1908, and she died suddenly on October 4th. I made very full notes of her case, with cardiographic tracings, which were verified at the necropsy. I did not see her for the last ten days of her life, as I was on holiday. She must have had several attacks of auricular fibrillation, which was not then usually recognized as a clinical entity, though many years previously Professor MacWilliam had experimentally produced it in animals. At that time we were examining the blood of most patients for calcium. Her blood was examined several times by my clinical assistant and the house-physician, Dr. Pantland Hick and Dr. Gerrard. On only one occasion were the free calcium ions found to be normal. The following is abstracted from the notes of the post-mortem examination made by Professor E. E. Glynn: "Heart 14½ ounces; auricles normal. Right ventricle slightly hypertrophied and dilated; valves normal. Left ventricle hypertrophied and cavity smaller than right; mucous papillæ thick; mural orifice admits two fingers, mitral cusps thickened, and a hard calcareous nodule about the size of a pea in the posterior cusp. Aortic valves normal. A section of the heart muscle stained with osmic acid showed no evidence of fatty degeneration." I said that I could see no reason why this heart should have stopped in diastole unless there was a deficiency of calcium. Accordingly Pantland Hick took 5 grams of the muscle of the right and left ventricles respectively, and macerated each in 5 c.cm. of decinormal hydrochloric acid. He then examined for calcium according to Blair Bell's method and found that the muscle from the right ventricle gave an index of 0.3, and that from the left 0.7. By this process the whole of the lime, fixed and free, was extracted so the amount of free calcium in the muscle was very scanty. This was a lesson for me from which I hope I profited.

I was the first to discover that by *plucking* Abrams's cardiac reflex of contraction I could arrest an attack of auricular fibrillation in five minutes, but this is not a cure; the reflex must be frequently repeated to prevent overloading of the right auricle and recurrent fibrillation, until the heart is well charged with calcium. To prevent repeated attacks digitalis, strophanthus, and pilocarpine can be used. The old Guy's pill to which has been added one grain of quinine sulphate answers admirably. This pill should only be continued for a short period. A tonic of

pilocarpine, strychnine, quinine, phosphoric acid, and syrup of the glycerophosphate of calcium is useful at any time. If there be any respiratory distress, pain, or insomnia we should not hesitate to give a hypodermic injection of omnopon or morphine. I have never prescribed quinidine, because I think the patient runs sufficient risks without the additional one of poisoning. In these cases there is always a deficiency of calcium, and some absorb it very badly, so you should regularly examine the urine for lime salts. Ringer's solution containing about double the usual amount of calcium chloride and two ounces of the syrup of glucose to the pint is an excellent beverage which should be drunk freely or used for diluting milk.

Enormous numbers of cases of heart disease got rapidly well after the armistice. How is it that since then not only the incidence but the mortality from diseases of the circulatory system has so increased that they have now become, in Osler's language, "the captain of the men of death"? Cardiac failure is now the medical explanation of sudden death; but why does the heart suddenly fail? It is a wonderful self-repairing pump, which can execute an enormous amount of extra work, and will not give out on slight provocation.

In conclusion, I strongly advise you to maintain a healthy and efficient circulatory system, and the heart will take care of itself. Your studies must be along the lines of biophysics and biochemistry. Look at the enormous strides which have been made in physics during the present century. If you wish to move in the van of progress you must educate yourselves; if you trust on the medical schools you are leaning on a broken reed. Associate with physicists and you will learn something worth knowing. There is one book which I would like you to read, *The Bipolar Theory of Living Processes*, by George W. Crile, the great American surgeon. Be constantly on the look-out for something true, whether new or not. "Receiving a new truth is adding a new sense," though "there are few persons to whom the truth is not a sort of insult." I have often said to my professional brethren, Do not advertise; cure your patients and they will advertise you. It has been often said, with more or less truth, young men kill their patients, old men allow them to die. I counsel you to steer a middle course and keep them alive. Not only keep them alive, but keep them for ever in your debt by the maintenance of their health. Patients are not so ungrateful as some people imagine.

ACUTE PERFORATION OF THE STOMACH AND DUODENUM.

A CRITICAL REVIEW OF THE RESULTS OF OPERATION.

BY

A. GRAHAM BRYCE, F.R.C.S.,

SURGEON TO THE PARK HOSPITAL, DAVYHULME, AND THE MANCHESTER JEWISH HOSPITAL; ASSISTANT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

FINALITY has by no means been reached in the discussion on the best routine treatment of perforated gastric and duodenal ulcer, and it may therefore not be out of place to consider the results obtained in a series of cases in which the conditions of technique and after-treatment were constant.

The series comprises 154 cases. The method of treatment was to invaginate the perforation by two layers of suture and to strengthen them by an omental graft. At the pylorus and in the duodenum the suture line was made to lie in the transverse axis of the bowel. Immediate gastro-enterostomy was not practised as a routine, and was, in fact, only performed in three of the cases. In one patient the perforation was converted into a gastrostomy by the insertion of a tube drain. Peritoneal drainage—usually suprapubic—was employed in about one-third of the cases, and more frequently in the earlier than in the later ones. All the patients were admitted to the Manchester Royal Infirmary, and it is to the members of the honorary surgical staff of that hospital that I am indebted for the opportunity to operate upon and report these cases. The series is consecutive in the sense that it includes all those patients whose condition warranted laparotomy and on whom it fell to my lot to operate during the years 1924-27. Their number is one which may perhaps fairly be said to indicate the average results of a uniform method under present-day conditions, when early diagnosis is the rule. It is to general practitioners who make this early diagnosis that any improvement shown in modern mortality figures is largely due.

Symptomatology.

One or two features of the clinical picture merit mention. Many writers—Moynihan[1] most insistently—have emphasized the point that a rapid pulse rate is not necessary for the diagnosis of perforation, yet a normal pulse rate certainly continues to cause hesitation, which may have disastrous consequences. There may occur an actual slowing of the pulse rate, which has been ascribed by Kreckе[2] to stimulation of the vagus. In 40 of 129 cases of this series in which the pulse rate was recorded it was from 60 to 80 beats per minute. The absence of acceleration is perhaps specially evident during the "delusive interval," which occurs typically, though by no means constantly, between the fifth and twelfth hours after perforation.

Adamson, Oehlecker,[6] Morley,[3] and others have described shoulder-tip pain as a help in differentiating perforated ulcer from other acute conditions. Of 108 patients in this series in whom this point was investigated, shoulder pain was present in 74 and absent in 34. In only 52, however, was the pain at the point of the shoulder on one or both sides. In the others it occurred in the clavicular region, in the neck, or between the shoulder-blades. De Bruïne Ploos van Amstel[4] places little reliance on this symptom, and it may be admitted that it is neither constant nor pathognomonic. Yet the typical rigidity and dramatic onset may fail, as Cuendet[5] and others have pointed out. In just such cases I have found shoulder pain a useful and comforting help in deciding on laparotomy.

Continental writers have described a pre-perforation stage with severe and uncontrollable epigastric pain as its main symptom. This is regarded as an absolute indication for surgical intervention, yet Schoemaker[6] had a patient perforate on the night following a prophylactic gastro-enterostomy. In four of the cases here reported the history suggests that such a pre-perforative stage had existed. But it seems doubtful if this condition is more than an exaggeration of the ordinary "attack of ulcer" which frequently heralds perforation, as it did in 64 out of 77 cases in which a note on this point was made. In 10, perforation was the first sign of the existence of an ulcer.

One visualizes the "perforated" patient as suddenly and completely incapacitated. This is not always the case. After the onset of the excruciating pain, four of these patients walked varying distances of from eighty yards to one mile, three "walked home," one continued to work for a few minutes and then climbed down from a roof, and one drove a motor car for three miles.

Of importance in the matter of workmen's compensation is the influence of strain as a causative factor. In one patient (carcinoma of the stomach) the ulcer gave way

during a fit of coughing. Another patient, whose ulcer was in the duodenum, was in the act of lifting a heavy weight when seized with the classical pain. I have seen at least two other cases in which the relationship of effort appeared to be indisputable. This relationship has previously been described by many writers,[4] (Powers[5]), but the connexion must be immediate and undeniable before effort can be admitted as an etiological factor. It is interesting, but out of place here, to speculate on the mechanism of its action.

Sites of Perforation.

Owing to inflammatory infiltration it is not always possible to say whether a perforated ulcer is proximal or distal to the pyloric vein. Stenbuck,[3] Fermand,[7] and Cuendet have drawn attention to this difficulty. The matter is not one of merely academic interest. Many Continental writers seem to classify pyloric ulcers as gastric. This may lead to erroneous conclusions in assessing mortality, and considerable difference of opinion apparently exists on the relative dangers of leakage from the stomach and the duodenum. Iserlin states that duodenal perforations have a better prognosis; Petren and Brunner hold the opposite view. Glaessner and Rosenthal,[4] and Meyer and Brams,[10] say that there is no difference. In order to be clear on this point I have classed all those perforations at the pylorus which were not definitely in the duodenum as pyloric. All the duodenal ulcers were in the first part, and no case of jejunal perforation is included in the series. One duodenal ulcer was on the posterior wall, and one lesser curve ulcer had opened into the lesser sac—in both cases the escape of fluid was minimal. This lesser curve perforation, one duodenal, and one pyloric perforation, were the second from which the respective patients had suffered. Whether in any of them the same ulcer had given way for a second time could not be determined, but a report of Borszeky's[11] demonstrates the possibility of such an occurrence.

Mortality.

Of the 154 cases, 20 died, making a mortality of 12.9 (say 13) per cent. The lesion was in the duodenum in 100 cases (8 deaths, 8 per cent.), at the pylorus in 33 (5 deaths, 15.1 per cent.), and in the stomach in 21 (7 deaths, 33.3 per cent.). Six of the stomach cases were malignant.

TABLE I.

Time between Perforation and Operation.	Number of Cases.	Deaths.	
		Number.	Percentage.
A. *Perforated Duodenal Ulcer.*			
Twelve hours or less	81	6	7·4
More than twelve hours	19	2	10·5
B. *Perforated Pyloric Ulcer.*			
Twelve hours or less	29	3	10·3
More than twelve hours	4	2	50·0
C. *Gastric Perforations.*			
Twelve hours or less	17	4	23·5
More than twelve hours	4	3	75·0
D. *All Cases.**			
Six hours or less	75	4	5·3
Six to twelve hours	52	9	17·3
More than twelve hours	27	7	25·9

* This section shows the importance of the time factor.

In the twelve-hour groups the cases of duodenal and pyloric perforations treated without gastro-enterostomy show an almost identical mortality, between 7 and 8 per cent. Probably nearly all the pyloric ulcers were in fact duodenal. No attempt will be made here to force conclusions from small groups of case reports, but the figures support the view that gastric perforations are considerably more lethal than those in either of the other two situations—a matter of common knowledge to any experienced hospital sister. It is also interesting to note that the group of perforated carcinomata (6 cases under twelve hours) showed a better operative recovery rate than that of the non-malignant gastric perforations (11 cases under twelve hours).

The recent collective investigation into the after-history of gastro-enterostomy[12] undertaken by the British Medical Association showed the mortality in 112 cases of perforated duodenal and pyloric ulcer in which gastro-enterostomy was performed to be 13.6 per cent. Unfortunately no details are given of the stage after perforation at which operation was done, and comparison is therefore difficult.

Late Results.

Of the cases treated without gastro-enterostomy, 163 have been followed up for periods varying from eighteen months to four years and nine months from the date of operation. All those in the "quite free" class have been followed up for at least two years. Of the 163 patients, three have died, two from carcinoma of the stomach and one (duodenal) from an unknown cause. The remaining 160 cases may be classified as follows:

TABLE II.

	Duodenal.	Pyloric.	Gastric.	Total.
(*a*) Quite free from any kind of stomach trouble.	27	5	0	32
(*b*) Have or have had slight symptoms, certainly or possibly attributable to ulcer, but not justifying operation.	13	6	2	27
(*c*) Have ulcer symptoms which do or might by some be held to indicate operation.	15	10	1	26
(*d*) Have had a second operation for ulcer ...	9	4	2	15
Total	72	25	5	100

In Class (*a*) 21 patients have been free from symptoms for from two to three years, 10 have been free for from three to four years and nine months. An ulcer patient must always be liable to the risk of recurrence of symptoms, and the two-year period was taken for purposes of this follow-up for the following reason. Of 48 patients in whom recurrence took place and who stated the period of respite, in only 4 was it more than one year and nine months. It seems likely, then, that any return of symptoms after simple closure of a perforation will take place within two years.

Of the 160 patients, 65 have worked regularly since operation, 15 have been unemployed or have lost work but not on account of symptoms ascribable to ulcer, 20 have lost work on account of ulcer symptoms.

The Question of More Extensive Immediate Operations.

In this country controversy has centred on the advisability of immediate gastro-enterostomy. The question is one on which it is impossible to dogmatize. Much depends on the views of the operator as well as on the condition of the individual patient. Gastro-entero-stomy has been said to diminish the death rate in the acute stage. Radoiévitch,[13] in a thoughtful paper, says that simple closure of perforated ulcers gives a higher initial mortality—23.5 per cent. within the first twelve hours and 61.4 per cent. after that interval—than any of the more extensive procedures, including partial gastrectomy. Grey Turner and Dunhar[14] state that primary gastro-enterostomy increases the mortality, and Zachary Cope[15] uses this method less than he formerly did.

Various other advantages have been claimed for the extended operation in the acute stage, notably that it does away with the danger of stenosing the pylorus. I have been able to observe some hundreds of cases of perforated ulcer, operated upon by different surgeons, and do not remember ever having seen pyloric stenosis in the immediate post-operative period unless it had previously existed; but Rayner[16] and Radoiévitch cite indisputable cases of this complication after suture alone. Many writers have pointed out its rarity, and the elaborate methods necessary to attain occlusion of the pylorus when it is deliberately undertaken make their statements easy of credence. The fear of stenosis should not be a reason

for systematic gastro-enterostomy at the primary operation. The supervention of pyloric stenosis as a remote complication will be mentioned later.

That a short-circuit may relieve tension on the suture in large callous (especially gastric) ulcers appears probable. The technical difficulties of closure in certain of these cases are very great and time-consuming—a fact used with some force by those who press for radical measures in the acute stage.

Most British writers advise suture alone as the routine procedure (Berry, Rowlands, Legg,[14] Adams,[18] Pannett, etc.), and even the advocates of anastomosis (Mills,[19] Evans,[20] Sherren,[14] and others) point out that it is not a method for every operator. The condition of the patient has an obvious importance, though the necessity for extreme speed in operating may have been exaggerated.

But perhaps the most attractive argument for immediate gastro-enterostomy is contained in the statement that its remote results surpass those of simple closure. Dunbar, however, did not find any great permanent benefit to follow the combined operation, and it is interesting to note that its alleged unsatisfactory end-results have been advanced against gastro-enterostomy by those who favour immediate resection of the stomach (Nyström,[21] Kreuter[22]). It has also been claimed[13] that reperforation, of which three cases are here reported, would be prevented by complementary gastro-enterostomy. Platou[23] records three cases of reperforation within one year of simple closure of the original perforation.

If it had been possible to undertake the combined procedure in the 100 cases mentioned in Table II, and if they had all remained quite free from symptoms, at least 32 of them would have undergone an unnecessary gastro-enterostomy for the benefit of the remainder. Each individual surgeon's practice will be governed by the answer which he finds to the question implied in this fact: assuming the improved mass end-results, is one justified in obtaining them by submitting a considerable minority of patients to an operation which is, to them, unnecessary? It may be argued, not illogically, that one is justified. It may also, with at least equal logic, be argued that one is not justified in submitting any patient unnecessarily to an operation of which Hurst[24] has said that it is the commonest gastric disorder of the day, even though one may not take such a gloomy view of it as he does. Pannett[25] has pointed out that patients whose ulcers perforate seem prone to the formation and perforation of anastomotic ulcers, and Bolens[26] instances some striking examples of repeated perforations at the anastomotic line. (See also Riess, Ashcroft, Ehrlich, Porzelt, Butler, Robinson, and Nixon and Lowry.[27])

Should one decide that the ability of the patient to bear it should not be the sole indication for something more than mere closure of the perforation, are there any guiding factors to help one in the selection of cases? Existing pyloric stenosis, and the probability that it will occur in the process of healing, are obvious indications. The later development of pyloric stenosis certainly occurs frequently enough to demand consideration. Induration of the ulcer and chronicity of symptoms (by no means synonymous terms) are also indications, but do not point the way quite so clearly. K. P. Brown,[28] in opposition to most writers, finds that patients without previous symptoms have worse late results than those with long-standing dyspepsia. The following tables have a bearing on this point. In them are analysed 32 cases classed in Table II as quite free from stomach trouble.

TABLE III.—*Total Duration of Dyspepsia.*

	Cases.
No note	8
"Some"	5
Up to one year	5
Two to nine years	7
Perforation during first attack of dyspepsia ...	7

TABLE IV.—*Induration.*

	Cases.
No note	9
Absent	8
Present	15

The numbers are too small to allow any generalization, but it is clear that neither induration nor length of history affords an infallible guide as to whether suture alone will cure or not. It seems justifiable to suggest that, in the absence of stenosis, the selection of cases for primary gastro-enterostomy demands careful and mature judgement.

Of the more radical operations in the immediate treatment of perforated ulcer (excision or cauterization of the ulcer with or without gastro-enterostomy, sleeve resection, partial gastrectomy) I have no experience either as an operator or as an observer. The results claimed by Continental surgeons[29] seem to justify radical extirpation of an operable perforated carcinoma of the stomach if the general condition of the patient allows. Indeed, it was in such circumstances that Keetley[30] in 1902 first demonstrated the possibility of radical measures. If there is a class of non-malignant case in which the more extensive methods appear indicated in competent hands, it is that of the large indurated gastric ulcers in which faulty closure is only overcome by wide infolding, often after the expenditure of much time and with gross deformity of the stomach as a result. The mortality of suture in these cases is high, and it is conceivable that it might be reduced by the certain approximation of healthy tissues after removal of the infiltrated area. Much more rarely, extensive and callous duodenal ulcers call for similar treatment (Grimault,[31] Dunbar).

Conclusions.

1. The immediate mortality of treatment without gastro-enterostomy in 125 cases perforated for twelve hours or less was 9.6 per cent.; and in 26 cases perforated for more than twelve hours 26.9 per cent. It is suggested that these figures fairly accurately represent the average under present-day conditions.

2. In a two-year follow-up, 32 per cent. of patients stated themselves to be quite free from any kind of stomach trouble after suture without gastro-enterostomy.

3. The immediate results after suture alone in pyloric and duodenal perforations are practically identical. Secondary operation finds more frequent indication in pyloric perforations.

4. Closure must be safe. In exceptional cases safety may demand something more radical than mere suture, with or without gastro-enterostomy. If in a given case such extensive methods are unjustified, careful apposition of the edges of the perforation by suture and the reinforcement of this by an omental graft are preferable to the infolding of a wide area of stomach-wall.

5. Apart from the cases mentioned under 4, gastro-enterostomy should usually be reserved for those cases in which stenosis is either actually present or likely to result from healing. In view of the fact that in other cases it is unnecessary in one out of three, it should not be done as a routine. The presence of an unnecessary gastro-enterostomy is not without risk, and it is better to await results and do it later if it should be necessary. Its systematic performance at the time of perforation without definite indication is certainly not likely to diminish mortality.

ON THE EXISTENCE OF A FOURTH HORMONE, THYREOTROPIC IN NATURE, OF THE ANTERIOR PITUITARY.

BY

F. A. E. CREW, M.D., D.Sc.,

PROFESSOR, ANIMAL GENETICS, EDINBURGH UNIVERSITY;

AND

B. P. WIESNER, PH.D.,

MACAULAY LECTURER, EDINBURGH UNIVERSITY.

RECENT investigation of the endocrine function of the anterior lobe of the pituitary has disclosed results which have converted earlier reasonable expectation into demonstrable fact. It is now established that extracts of anterior lobe, prepared in different ways, can produce the following diverse effects:

1. Excessive growth leading to gigantism.
2. Inhibition of oestrus.
3. Induction of oestrus.
4. Increase in the basal metabolism rate.
5. Metamorphosis in the neotonous amphibia.

The multiplicity and diversity of these effects naturally led to the assumption than more than one anterior pituitary hormone must be responsible for them, and so it is that some have attempted to *distinguish a growth hormone* and a sex or gonadotrope hormone (Evans and Simpson, 1928), whilst others have sought to analyse the latter into a hormone that promotes follicular development in the ovary and another which induces luteinization. By some it has been assumed that the growth hormone is antagonistic to the sex hormone—the oestrus-producing agent (Evans and Simpson); and that this antagonism explains away the fact that certain extracts containing the growth hormone actually inhibit the oestrus. Others have postulated that there are two oestrus-influencing factors involved, one inciting it, the other inhibiting it. The present writers, on the basis of their own experiments, have elsewhere succeeded in reconciling certain of these apparently conflicting opinions. They postulate the existence of two gonadotropic hormones of the anterior pituitary, Rho 1 and Rho 2 respectively, and refer the difference in gonadotropic effect to quantitative and qualitative differences in the preparation of these factors in any given anterior pituitary extract. Rho 1 is the oestrogenic factor, Rho 2 the kyogenic. The first incites in the ovary the first phase of activity, characterized by the elaboration of oestrin which leads to the phenomenon of cornification of the vaginal epithelium. Rho 2 evokes the second phase of ovarian activity, characterized by the activation in the ovary of the lutein tissue which elaborates substances that evoke the nidational potencies in the uterus, and mucification, the development of high mucous epithelium, in the vagina.

Evans and Simpson have shown that the growth hormone is not contained in human placenta, whilst Wiesner and Crew have demonstrated the presence of Rho factors therein. Since it has been found possible to obtain extracts which contain both Rho factors, but which do not contain the growth hormone, and since it is possible to extract Rho factors with acid as well as with alkaline media, whereas the growth hormone is not present in acid extracts (Hewitt), it follows that the Rho factors and the growth hormone are distinct and separable.

It has been shown by Adler, Allen, Spaul, and others, that certain anterior lobe extracts invoke metamorphosis in the neotonous amphibia. The question thus arises as to which of the known hormones of the anterior pituitary is responsible for this effect, for if none of these produces metamorphosis, then it becomes necessary to postulate the existence of yet another anterior lobe hormone responsible for this phenomenon. It is established that thyroxine can induce metamorphosis, but it is most unlikely that the hormone of the anterior pituitary which produces metamorphosis is identical with this substance (Spaul). Since the feeding of large amounts of anterior lobe can promote growth in the axolotl in the absence of metamorphosis, it would seem that the metamorphic factor is not the same as the growth factor. It is of interest to note that Spaul has produced evidence which shows that there exists a different regional distribution in the pituitary of this growth factor and of the metamorphic factor.

In order to examine the question as to whether or not Rho 1, Rho 2, or the growth hormone was identical with the metamorphic factor, the following experiments were planned. To different sets of young axolotl, three in each, the following substances were administered, 0.5 c.cm. being given daily over a period of a month: (1) thyroxine; (2) extracts of human placenta prepared by the method of Wiesner (1930) containing Rho 1 and Rho 2, and known to be highly oestrogenic; (3) extracts of anterior lobe containing the growth factor prepared by the method of Evans and Simpson. Only those animals which received thyroxine metamorphosed. Since it has been shown that the presence of posterior lobe derivatives in an anterior lobe preparation leads to a retardation of the metamorphic effect, it might well be that in these extracts posterior derivatives were present, and the failure of Rho factors to induce metamorphosis might be due to a secondary cause.

But a further series of experiments permitted us to arrive at certain definite conclusions. It is to be noted that the active extracts of Spaul and others—for example, of Uhlenhuth—are prepared by boiling anterior lobe in diluted acetic acid for ten minutes. Now it had been observed that the Rho factors are completely destroyed if boiled for more than three to five minutes. In accordance with these observations we found that extracts prepared by Spaul's method and injected in various doses into immature mice proved to be inactive. In no case did cornification or mucification of the vaginal epithelium follow: though extracts prepared with acetic acid without boiling definitely activate the ovary and thus lead to significant changes in the vaginal epithelium. It follows, then, that the extracts prepared by Spaul's method do not contain the Rho factors. Boiling also destroys the growth factor, as was found by Evans; and it is of interest to note that Spaul states that the use of alkaline media is detrimental to the preparation of the metamorphic factors, though this has been shown to be the best method for the extraction of the growth factor (Evans, Hewitt, Putnam, Teel).

There would seem, then, to be no escape from the conclusion that there must be at least four hormones elaborated by the anterior pituitary—*the growth factor, two gonadotropic factors (presently called Rho 1 and Rho 2), and a metamorphic factor*, which we think provisionally should be given the name of Theta.

Since metamorphosis is produced in the neotonous amphibia by the mammalian pituitary, it follows that the theta factor *is present*, even in those forms in which metamorphosis *does* not occur. What, then, is its role?

Certain observations suggest that this theta factor is *thyreotropic* in its action, being the activator for the release of thyroid development and activity. It has been shown by Uhlenhuth and Schwarzbach that the thyroid of an animal metamorphosed by anterior pituitary undergoes that series of developmental changes which are characteristic of normal metamorphosis. Moreover, it has been noted by Allen and others that the thyroid of *hypophysectomized* animals becomes atrophied. It is true that Hoshen and Spaul have both recorded instances of metamorphosis induced by anterior pituitary extract in the thyroidless individual, but it would appear that this metamorphosis was not complete in the first author's cases, and, as Uhlenhuth has pointed out, it is not yet decided that in these experiments the thyroid was completely removed. This view is supported by certain other facts. Extracts of anterior lobe which induce metamorphosis also provoke a rise in the metabolism of the frog (Uhlenhuth). This is as would be expected if the extracts contained substances which stimulated the thyroid, or if the metamorphic factor in the anterior pituitary were thyreotropic in action. Moreover, it has been reported by Smith

that the degenerative changes in the thyroid following hypophysectomy are repaired following implantation of anterior lobe substance.

Uhlenhuth would seem to be justified, therefore, in ascribing the metamorphic effect of anterior lobe extracts to the presence of an activator of the thyroid therein. Be that as it may, our own experiments show that not only is the metamorphic factor not identical with the growth hormone—as has been concluded by Spaul—but that it also differs from the gonadotropic hormones. It may be assumed, therefore, that a fourth anterior pituitary hormone (theta) exists. Further experiments will have to show whether it is thyreotropic, as it seems to be.

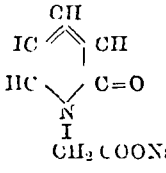
INTRAVENOUS PYELOGRAPHY.

BY

E. J. H. ROTH, M.R.C.S., L.R.C.P., D.M.R.E.,

RADIOLOGIST TO ST. PETER'S HOSPITAL AND TO THE GERMAN HOSPITAL;

AND



H. W. S. WRIGHT, M.S., F.R.C.S.,

ASSISTANT SURGEON TO THE GERMAN HOSPITAL AND TO THE EAST LONDON HOSPITAL FOR CHILDREN.

EVER since Ehrlich in 1906 produced salvarsan, scientific workers all over the world have been looking for an antiseptic which, when injected intravenously, shall be harmless to the body tissues and yet be able to kill micro-organisms. Their ideal has never yet been realized, but many useful synthetic products have resulted from their search. Uroselectan (sodium 2 oxy-5-iod pyridine-N-acetic acid) is one of these.

For some years prior to 1928 Professor Binz and Dr. Raeth had been experimenting with an organic compound of iodine selectan-neutral, which, it was hoped, would be of use in coccal injections of the biliary and urinary tracts. Erbach, moreover, had shown that this compound, with a high molecular weight, was excreted in part by the kidneys, and naturally these facts suggested that it might throw a shadow of the urinary tract on radiographic examination.

Experiments to this end were carried out by Swick[1] in Lichtwitz's clinic, with only more or less satisfactory results. The clarity of the shadows was variable; they were not sufficiently dense for reproduction, and it was found that, whether the compound was administered by the mouth or intravenously, there was a good deal of individual variation in tolerance. Furthermore, a large number of reactions, such as headache, sickness, and vomiting, were recorded. For these reasons it was later on suggested by Swick and von Lichtenberg that sodium glycin should be substituted for a methyl group, and the solubility of the compound increased by a slight reduction of the iodine content. This work was carried out by Binz and Raeth,[2] and the compound called uroselectan was the result. The formula of the preparation is shown below.

Chemical and Physical Properties.

It is neutral, soluble in water to more than 50 per cent., and contains 42 per cent. of iodine. Its opacity to x rays is shown in Figure 1. It is an extremely stable chemical compound, which can be introduced into the blood stream in relatively large amounts. If deductions from animal experiments[3] are reliable, it is possible to give an intravenous dose of 180 grams to a man weighing 50 kilos, but for clinical purposes 40 grams is all that is necessary to produce perfectly clear-cut shadows. This amount is dissolved in 80 c.cm. of redistilled water, filtered twice, and autoclaved for twenty minutes. The result is a heavy brown solution, which, however, contains no free iodine. Experiments have been made with a view to sterilizing it by boiling, and a solution boiled for three hours has been used with no ill effects. For children the dose is proportionately smaller. Up to the age of 6 we inject 10 to 12 c.cm. of the 40 per cent. solution; from 6 to 10 years, 20 to 40 c.cm.; and from 10 to 15 years, 50 c.cm.

Technique.

The patient is prepared for the x rays in the usual way, and a preliminary radiogram is taken. The solution at body heat is then injected slowly into a vein, preferably in two equal doses, at an interval of from two to three minutes. For routine purposes radiograms are then taken, a quarter of an hour, three-quarters, and one and a quarter hours after injection.

Generally speaking, the rate of excretion bears a direct relationship to the renal function, as determined by the ordinary tests, and after a quarter of an hour in cases with a good renal function, not only is the whole urinary tract clearly visible, but there is a definite increase in the normal renal shadow. This latter is naturally more easily appreciated in the film than in a reproduction. The standard of radiographic technique demanded is high. The shadow thrown by the drug as it is excreted by the kidney is not quite as dense as that ordinarily obtained by the introduction of media through ureteric catheters, and it is therefore of paramount importance that the maximum contrast should be obtained upon the radiogram. For this reason we use a low penetrating ray such as is emitted from a tube excited by a maximum potential of 65 kilovolts peak.

FIG. 1.—1. Uroselectan. 2. Half uroselectan and half 2 per cent. urea. 3. Half uroselectan and half 4 per cent. urea. 4. 4 per cent. urea. 5. Water. 6. 20 per cent. sodium iodide.

A Potter-Bucky diaphragm fitted with a pressure band in conjunction with double intensifying screens is used, the focal plate distance being thirty inches. With a milliamperage of 60, the exposure will vary with the bulk and build of the patient, and will ordinarily be from one to five seconds. The radiograms are developed for five minutes in a standard developer heated to 65° F. precisely. The radiograms when completed are examined in lanterns of equal illuminant power. No variation from the normal procedure is permissible.

It must be pointed out that important information is obtained by comparing radiograms of a series, and any variation in the relative density of the drug-laden urine must be independent of variations in radiological technique. Several of our patients were radiographed at three-minute intervals, and in one patient radiograms were obtained at intervals of five seconds. Should such procedures become general, and the results of more than academic interest, it may be necessary to devise serial changing cassette holders working in conjunction with a Potter-Bucky diaphragm. The cinemato-radiogram may in the future give the perfect serial visualization of kidney function.

CASE I.

This case indicates clearly the results which can be uniformly obtained in a patient with a relatively normal renal function. The radiogram (Fig. 2) shows a stone clearly outlined in the slightly dilated pelvis of the right kidney. The left kidney is normal. There was in this case no need for cystoscopy, although it was carried out as a check on a new method. Fig. 3 shows the slightly dilated pelvis of a movable kidney. The outline of the upper ureter and the increased density of the renal shadow are also clearly seen.

CASE II.

The radiogram (Fig. 4), taken after operation, shows clearly a filling defect in the lower calyx of the right kidney of a youth aged 19, who was the victim of a "buffer accident." His kidney was split in front and behind to a depth of 1 cm.

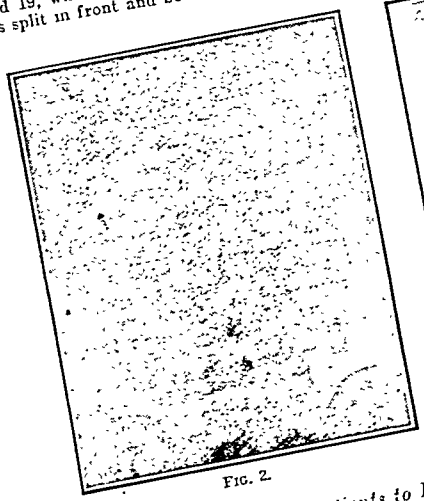


FIG. 2.

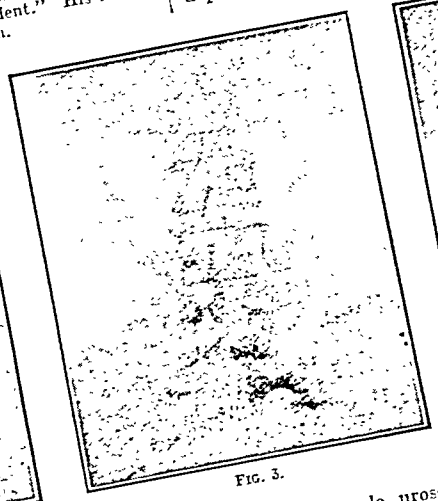

FIG. 3.

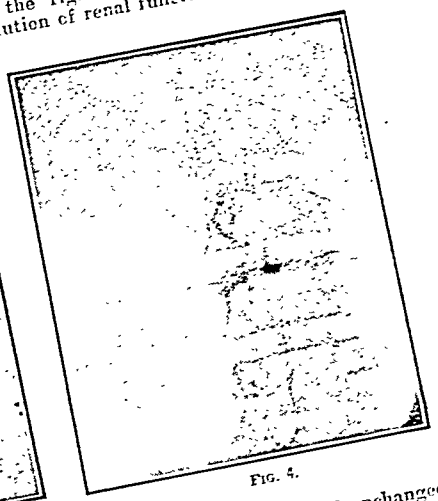

FIG. 4.

Reactions of Patients to Injection.

In our experience, and in that of others, the injections have been followed by no ill effects. Within a few minutes the pulse rate is increased by 10 to 15 beats to the minute and the blood pressure is raised 10 to 12 mm. of mercury. These both return to normal within fifteen minutes, and remain so. During this short period of raised blood pressure some patients complain of slight giddiness. Occasionally there is a transient cramp in the anterior shoulder muscles, but this is in no way distressing. A patient who was very nervous and complained of giddiness was easily able, immediately after injection, to stand up for screen examination. In one case a small quantity was injected outside the vein. From this accident no ill effects were observed. After injection no free iodine is found in the blood and urine, and in cases with a normal renal function no iodine can be found in the blood within a quarter of an hour of injection.

Experience has shown that the injection can be given perfectly safely even in cases with such a marked decrease of renal function that the dye has been retained in the circulation from twenty-four to thirty hours. The only known contraindications to its use are anuria, uraemia, and cases in which the liver as well as the kidney are grossly diseased. One death in such circumstances has been reported.[4]

General Consideration of Results.

Very often, owing to the rapidity with which the urine runs down into the bladder, the whole line of the ureter is not seen unless serial radiograms are taken. If, however, there is any blockage of the ureter from stricture within, or from pressure without, the ureter is easily visualized. Normal shadows sometimes show more dilatation than is usually visible with ordinary pyelography, probably because spasm due to the presence of a catheter is eliminated. In order to show up the lower ureter it is necessary to empty the bladder before making each routine exposure. We have not succeeded, as others have done, in visualizing on screen examination the pelvic shadow accurately enough for pyeloscopy.

Interpretation of Results.

In our series of about sixty radiograms we have noticed that the shadow of the left kidney appears slightly less dense than that of the right. This is apparently not dependent on a diminution of renal function.

As a rule, uroselectan is very rapidly excreted unchanged. We have serial radiograms taken at three-minute intervals after injection in several cases. Generally speaking, there is a satisfactory shadow after six minutes, and in fifteen minutes there is a perfectly clear outline of the whole of the urinary tract. In one case where radiograms were taken at five-second intervals all the major calyces were faintly but definitely outlined five minutes after injection. Within six hours 80 to 90 per cent. of the iodine is eliminated.

Dr. Obermer, to whom we are greatly indebted, has been unable to find any trace of free iodine in the urine of patients after injection. Fig. 5 shows the relative opacity of the urine secreted at varying intervals.

Uro-selectan is easily recovered from the urine. On the addition of hydrochloric acid it forms a heavy white precipitate when the *p*H reaches 2·8 to 3. It can therefore be used as a good test of renal function. Chemical estimation, however, is not always necessary, because, as Fig. 5 shows, the specific gravity is a very reliable guide to the amount of the drug present. It should reach between 1045 and 1050 within an hour, during which period the bulk of the drug is excreted. Whether, as a test of renal function, it is as reliable as the indigo-carmine or the urea concentration tests, remains to be seen. There exist facts which suggest that infection is much more potent in retarding its excretion than that of indigo-carmine.

Von Lichtenberg states, and our experience confirms his view, that while an advanced non-infected hydronephrosis will give an excellent though perhaps delayed shadow, a pyonephrotic and infected or a congested kidney may give no shadow at all.[5]

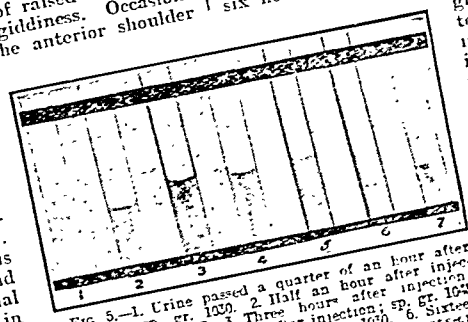

FIG. 5.—1. Urine passed a quarter of an hour after injection; sp. gr. 1030. 2. Half an hour after injection; sp. gr. 1037. 3. Three hours after injection; sp. gr. 1045. 4. Five hours after injection; sp. gr. 1030. 5. Ten hours after injection; sp. gr. 1027. 6. Sixteen hours after injection; sp. gr. 1015. 7. Twenty-one

CASE III.

The radiograms in this case (see Fig. 6) illustrate excellently how an infected kidney may fail to yield a shadow. The right kidney pelvis, which filled within a quarter of an hour, is dilated, and shows cupping of the calyces, possibly due to an infection. There is no uroselectan shadow of the left kidney, but the faint outline of multiple calculi can easily be seen. At biopsy, after operation, multiple chronic staphylococcal abscesses were found scattered throughout the renal cortex.

FIG. 6.

Finally, to assess the value of uroselectan is at the present moment impossible, but being both a reliable renal function test and a pyelographic contrast medium, it is bound to play an important part in urological diagnosis. Von Lichtenberg[6] states that in 70 per cent. of 84 cases its use eliminated the necessity of cystoscopy. From the patient's point of view this in itself is the greatest possible advantage.

In cases where cystoscopy and catheterization of the ureters is difficult or impossible its routine use will be a necessity—for example, in children, and patients with ureteral strictures or pelvic tumours which compress the ureters from without. In cases of movable kidney it is easy to estimate the degree of mobility because the patient can stand up, or, in fact, assume any position that circumstances may require.

The disadvantages are two—namely, its expense, which is considerable, and the fact that no shadow is obtained when the renal function is greatly diminished.

It is probable that in the future intravenous pyelography will invariably be carried out before the decision is arrived at that the patient must be submitted to the ordeal of ureteric catheterization.

SWELLING OF THE FEET AND ANKLES NOT ASSOCIATED WITH ALBUMINURIA OR GROSS ORGANIC DISEASE.

PATHOGENESIS AND TREATMENT OF A COMMON SYMPTOM.*

BY

A. ARNOLD OSMAN, *D.S.C.*, M.R.C.P.LOND.,

CONSULTING PHYSICIAN, GREENWICH AND DEPTFORD HOSPITAL; PHYSICIAN, QUEEN MARY'S HOSPITAL, E.; SENIOR MEDICAL ASSISTANT, GUY'S HOSPITAL.

OEDEMA without albuminuria occurs in a variety of well-known conditions, such as several of the anaemias, chlorosis, war oedema, starvation oedema, beri-beri, and varicose veins in the legs. It also not infrequently precedes the appearance of albuminuria in the early stages of some cases of nephritis and pregnancy kidney. The type of oedema which is described here, however, is one which is quite commonly met with, especially among patients of the so-called hospital class, though it is by no means confined to them. It cannot be ascribed to any of the conditions already enumerated, and is seen chiefly in adult women, in the form of "puffiness" or swelling of the feet and ankles. It is, however, occasionally met with in debilitated adult males, and even in children. In women, not always of the poorer classes, it is the cause of much misery and distress, partly for cosmetic reasons, and also because in bad cases walking is difficult or impossible, and so leads to loss of employment. Tennis and dancing also have frequently to be given up because of this symptom. The milder cases do not seek advice for this, but for associated symptoms of that state of subnormal health commonly called "debility," such as headaches, constipation, lassitude, amenorrhoea, etc. Other patients complain chiefly of swelling of the feet, and are diagnosed as cases of anaemia, and iron, tonics, and various glandular extracts are prescribed. Some of the wealthier resort to beauty parlours, where they are given massage and local hypertonic salt compresses. As a rule none of these measures appears to be very effective in affording relief for this exceedingly common symptom.

The Pathogenesis of "Swollen Feet."

There are, of course, several varieties of "puffy," swollen, or "thickened" feet and ankles which are not associated with cardiac, renal, or other gross organic disease. In some cases the swelling is due entirely to an increase in the water content of the tissues of the part, in others to excess of fat, and again in others to a combination of excess of both water and fat. There is also the variety associated with blueness of the extremities, referred to by Parkes Weber[1] under the descriptive title of "erythrocyanosis crurum puellarum." No hard-and-fast line can be drawn between these conditions in many cases, but this paper is concerned only with the enlargement of the extremities, generally the feet and legs, due to true oedema, or excess of water in the tissues.

As will be seen later, there is reason to believe that the relative frequency with which the oedema is complained of in the feet and ankles is probably due entirely to the effects of gravity, as in reality the excess of water, or oedema, is present in all the tissues of the body, though often not in sufficient amount to attract attention. During the course of the day the oedema tends to drain down to the feet, and by the evening has there collected in sufficient amount to be noticed by the patient.

The following case is typical of the disorder which is being considered here.

A lady, aged 36 years, was sent to the out-patient department complaining of pains and swelling in the feet and legs, most marked in the right ankle, which she had noticed for several months. The swelling was most prominent in the evening, and had usually almost disappeared on rising in the morning. The periods were regular, but rather scanty. The swelling was always much worse at the time of the menstrual periods. She had frequent severe headaches and a tendency to constipation. Six months ago she had lumbago, the only definite illness she remembered having had in her life. She was pale, and the complexion was "greasy" and spotty. The hands were not swollen or blue, but were clammy and sweaty. Examination of the heart revealed nothing abnormal, and there was no albuminuria. There was no obvious focus of sepsis. She was unmarried. The blood pressure, blood urea, and urea concentration were all normal. A blood examination, for which I am indebted to Dr. L. Hewlett, showed: red blood cells 5,936,000 per c.mm., haemoglobin 90 per cent., colour index 0.8. The plasma bicarbonate was 0.0278 M. (normal=0.0300 M.). The urine contained no albumin. It is clear, then, that in this case neither heart disease, kidney disease, nor anaemia provides an adequate explanation of the oedema. The latter was not sufficient to prevent walking, but it was of that degree which would have attracted the attention of lay persons.

Elsewhere[2] it has been shown that "debility," whether occurring in children or adults, is a state which is generally associated with some degree of "acidosis," which, in turn, is frequently accompanied by an increase in the water content of the body as a whole. The term acidosis was defined as a reduction of the concentration of bicarbonate in the plasma, and therefore does not necessarily imply any change in reaction (*p*H) of the blood.

It is suggested here that it is this underlying "acidosis," the exact cause of which is not known, which leads to excess of water in the tissues, and that in minor degrees of the disorder the accumulation of fluid is only sufficiently great to attract attention under the influence of gravity, and hence the frequency with which it apparently occurs in the feet and ankles alone. Taking the group as a whole, there is a considerable diminution in the plasma bicarbonate values in these waterlogged subjects, compared

* From the Medical Investigation Departments of Queen Mary's and Guy's Hospitals.

with the normal, which is probably not due to hydraemia or wateriness of the blood, as then the haemoglobin percentage would also be reduced.

It may be mentioned that a normal plasma bicarbonate may be present at the same time as a true "acidaemia," or change in reaction (pH) of the blood to the acid side of normal; and, further, that a normal reaction in the blood does not necessarily preclude an abnormal reaction in the tissues. The results of treatment in some of the cases described below, where the plasma bicarbonate was normal at the time treatment was commenced, suggests that "tissue acidosis" may have been present all the time. In the paper referred to above[2] it has been shown that the plasma bicarbonate is highest in normal adult males, and that it decreases slightly in the following groups in the order given: normal adult females (menstrual values), normal adult females (menstrual values), debilitated adult females, and normal pregnancy. It was pointed out, too, that the plasma chlorides, and the water content of the body, as measured chiefly by the frequency with which clinically apparent oedema occurred in each group, tended to increase in inverse relation to the plasma bicarbonate—that is, oedema, unaccompanied by albuminuria, was most often encountered in pregnancy, then in debilitated females, in normal women in between the menstrual periods, in normal women during the menstrual period, in debilitated adult males, and least often in normal adult males. This is certainly in accordance with clinical experience, and to some extent has been confirmed by more accurate methods.[2] These points are well brought out in Table I.

TABLE I.

Group.	No. Cases.	Average $NaHCO_3$	Average NaCl.	Water Content.
		M.	Gram %	
Normal adult males	86	0·0320	0·587	Least.
Normal adult females (intermenstrual)	31	0·0301	0·5685	+
Normal adult females (menstrual)	31	0·0291	0·591	++
Normal children	38	0·0299	0·606	+++
Debilitated children	63	0·0276	0·603	+++
Debilitated adult females	72	0·0271	0·594	++++
Normal pregnancy	68	0·0247	0·595	+++++

The type of oedema described in this paper occurs mainly in the feet, ankles, and legs, is at its maximum in the evenings, is worse after exertion and in hot weather. It may be constantly present, waxing and waning with the factors just mentioned, or may only occur under some of these conditions, disappearing apparently spontaneously for weeks or months at a time, and then perhaps recurring. It should be noted that those conditions—menstruation, exercise, etc.—which are associated with an increase in the oedema are also those usually accompanied by a decrease in the plasma bicarbonate.

Treatment.

The rationale of the method of treatment adopted in many of these cases is an outcome of the theory of the pathogenesis of the symptom outlined above. It consists in giving sufficient alkali, in the form of equal parts of potassium citrate and sodium bicarbonate, by the mouth, to raise the, and to maintain the plasma bicarbonate at, a normal level, and possibly to increase the alkalinity of the tissues—at all events, to give enough alkali to promote a diuresis sufficient in amount to remove the excess water from the tissues. The method, in fact, is the same as that described in detail elsewhere[3] for the treatment of certain cases of nephritis accompanied by oedema, without the dangers incident to the giving of large doses of alkalis in the presence of grossly damaged kidneys. For reasons of space it is not possible to give details of all the cases here, but it may be said that of the 16 treated up to date, the oedema cleared up entirely in the 16 treated up to date, the relapsed, and the oedema returned on discontinuing the treatment. Of these 6, 4 were again cured on resuming their former dose, and in 2 all further treatment completely failed to remove the oedema, though it was slightly improved in 1 of them.

It must be noted that; with two exceptions (Cases vi and vii), all the patients were attending the out-patient department for treatment, and most of them were meanwhile pursuing their usual avocations. There were therefore no control over the intake of fluid, the diet, or the amount of exercise taken. In many cases, too, the dose of medicine prescribed was not taken regularly. It is possible that the explanation for the lack of response to treatment in some of the cases may lie in one or more of the above factors; in any event it is not claimed that the treatment is always effective, but that it is so in a sufficient number of the cases to lend strong support to the correctness of the views put forward concerning the causation of the disorder.

From the practical point of view it is admitted that the treatment is tedious, clumsy, and not always effective; but, though it requires a good deal of supervision to get good results, it appears to be practically free from danger if confined strictly to the type of case under consideration. Further, estimations of the plasma bicarbonate are not necessary before or during treatment, provided there is no associated renal defect or accompanying dyspnoea or vomiting. Incidentally, it should be noted that, as in cases of nephritis with oedema treated by this method, there often occurs a preliminary increase in the oedema before final subsidence takes place.[3] Treatment, therefore, should be continued until this preliminary stage has been passed.

In detail, the treatment consists simply in giving by the mouth a mixture of 30 grains each of potassium citrate and sodium bicarbonate with 30 minims of syr. aurantii, in an ounce and a half of water, increasing the number of doses in the day according to need. It may often be necessary to give as much as 600 or 700 grains a day or more. With large doses, the strength of each individual dose may be increased to 50 grains of each ingredient per dose, thus allowing fewer doses in the day. It is probably wise to limit the intake of fluid roughly to a known amount in the twenty-four hours—say three or four pints, but no serious restrictions of fluids need be imposed. No other dietetic modifications appear to be necessary.

No untoward symptoms of any kind have been encountered in treating these cases in the manner described, except in one instance, where, for some reason unknown, the bladder became accidentally infected, and a cystitis resulted. The alkalinity of the urine appeared to favour the growth of the organism concerned, and treatment was therefore abandoned. The plasma $NaHCO_3$ was measured in these cases by the method of Van Slyke, Stillman, and Cullen,[4] the results being expressed as molar concentration.

TABLE II.

Case.	Sex.	Age	Duration of Oedema	Initial Plasma $NaHCO_3$	Maximum Daily Dose	Result
				M.	Grains.	
1	F.	32	18 yrs.	0·0270	400	Cured, relapsed, cured again.
2	F.	28	11 yrs.	0·0250	600	Cured, relapsed, failed to cure.
3	F.	25	2 yrs.	0·0224	500	Failed.
4	F.	24	1 yr.	0·0257	450	Cured.
5	F.	51	1 yr.	—	360	Cured.
6	M.	16	14 days	—	720	Cured.
7	M.	51	3 mths.	0·0237	360	Cured.
8	F.	19	3 yrs.	0·0265	1,000	Failed.
9	M.	48	4 mths.	0·0330	540	Cured, relapsed, cured.
10	F.	25	15 yrs.	0·0270	540	Cured, relapsed, cured.

12	F.	19	4 yrs.	0·0253	420	Cured.
13	F.	35	"Some yrs."	0·0223	480	Cured.
14	F.	23	"Some yrs."	0·0302	450	Cured, relapsed, improved.
15	F.	25	2 yrs.	—	360	Failed.
16	M.	44	10 wks.	0·0231	600	Cured.

Conclusions.

1. Analbuminuric oedema of the type described is most common in debilitated females.

2. It is generally associated with, and is probably due to, an underlying acidosis, with consequent increase in the water content of the body as a whole.

3. In many cases the symptom can be abolished by the giving of alkalis by the mouth in amounts sufficient to overcome the acidosis and promote diuresis.

4. The results of treatment confirm the thesis presented as to the pathogenesis of the disorder.

In conclusion, I should like to thank the many colleagues and friends who have helped me with the investigation of these cases, especially Dr. H. G. Close. I am indebted also to the physicians at Queen Mary's and Guy's Hospitals for sending me cases for investigation and treatment, especially to Dr. A. F. Hurst and Dr. H. French for access to Cases vi and vii respectively, and to Dr. J. A. Ryle for Case ii. My thanks are also due to Professor R. Donaldson and Dr. Arthur Davies, directors of the pathological laboratories of Guy's Hospital and Queen Mary's Hospital respectively; and, finally, to the Medical Research Council, for a grant enabling this work, which forms part of a larger investigation, to be carried out.

AFTER-HISTORY OF CASE OF GALL-STONES IN A YOUNG SUBJECT.

I. C., aged 24, was operated on at the age of 15 years for gall-stones, in May, 1920, by cholecystotomy (vide *British Medical Journal*, 1925, vol. i, p. 1126).

Following the operation she remained well till a year or two ago, when she began to experience spasmodic pain in the right hypochondrium. On August 13th, 1929, the scar became swollen and tender, and one week later the swelling burst, giving vent to green discharge containing numerous small stones. The pain subsided, but discharge of stones continued, sometimes as many as twenty at a time. She was readmitted to hospital on August 27th with a biliary fistula in the old operation scar, and with stones in the discharge.

Paramedian laparotomy showed gall-bladder adherent by fundus to site of the fistula. Cholecystectomy was performed, the subhepatic space being drained by a tube inserted through the fistula, and healing was uneventful.

Pathological Report.—Greatly thickened gall-bladder wall showed muscle hypertrophy and much inflammatory fibrosis, with cellular infiltration of subacute and chronic type. Mucosa showed abundant new formation of mucous glands.

MENINGITIS FOLLOWING OPERATION ON THE ANTRUM IN A PATIENT WITH COMPLETE TRANSPOSITION OF VISCERA.

THE case here recorded is of much interest, and seems worthy of publication.

A man, aged 24, seen during September, 1929, complained that he had been suffering from nasal obstruction for years, but that it had been very severe for the last two years. Examination revealed large multiple polypi on the left side. He was *x*-rayed. The films show an absent frontal sinus, but sphenoids, ethmoids, and both antra dull, especially the left.

He was admitted to hospital on October 15th, and examination confirmed the findings in the out-patient department, but also revealed the heart on the right side of the body. No other abnormality was detected.

On October 14th a Caldwell-Luc operation was carried out on the left side, and the polypi were removed through the antrum. A simple antrotomy was performed on the right side. He had an uneventful convalescence until October 21st, when he complained of headache and his temperature went to 102° F. A complete general and neurological examination was carried out, with negative findings. On October 22nd the condition was the same, except that his temperature was 100.2°, and again no other abnormality could be discovered. On the 23rd his temperature had fallen to 104° F., and he looked very ill. He was seen by the physician, who also found no other abnormality, but on account of his general condition ordered him three doses of 20 c.cm. polyvalent antistreptococcus serum at eight-hourly intervals. On October 24th he was given 50 c.cm. intravenous saline. The following day he had lung signs. The whole of the left lung, although normal to percussion, had an almost complete cutting off of breath sounds. Late that afternoon he had an epileptiform convulsion of the whole body. A blood culture was taken, and 10 c.cm. of 1/2 per cent. mercurochrome was given intravenously. By midnight he was having almost continuous epileptiform attacks, but they were gradually settling down to the left side of his face. These persisted in spite of 1/3 grain of morphine and a little chloroform inhalation. Lumbar puncture was performed. The fluid was under intense pressure, and 20 c.cm. were withdrawn. This had a few cells with intracellular bacilli resembling the influenza bacillus. He slowly sank, and died at 6 o'clock the following morning.

A post-mortem examination was carried out, with the following findings. The heart was lying on the right side. The spleen also was on the right side. The liver and appendix were on the left side. Both lungs were rigidly bound to the pleura throughout, and the large branch of the left pulmonary artery had an ante-mortem thrombus about three inches long. The brain had an area of pus over the whole of the upper part of the parietal lobe on the right side. The remainder of the brain, including the left side, was slightly congested but otherwise normal. A culture was made of the blood within the heart by Dr. Ponder, and was negative. The pus on the surface of the brain contained *Streptococcus longus*, and the thrombus was organized and infiltrated with leucocytes. We thank Dr. Ponder for the many bacteriological and microscopical examinations.

I wish to thank my honorary surgeon, Mr. J. Aldington Gibb, for permission to publish this case, and also for the following note.

"The operation performed by me was so usual and uncomplicated that the possibility of traumatic involvement never entered my head. The occurrence of two consecutive cases of erysipelas in the ward at the time may have been the source of infection. Moreover, the heating apparatus failed at the time, which inclines me to the view that this may have been an exciting cause of the onset. Mr. Mitchell, the house-surgeon, was unremitting in his care of the patient, and the post-mortem findings are his entirely, for which he deserves any credit. The case is interesting and well worthy of publication."

It was interesting to note that there was no macroscopic evidence of the disease having tracked up from the nose by a direct path, but it was completely isolated high up on the right side of the brain; also that the man was passed for the police force as perfectly fit in spite of his complete dextrocardia, and that he had done hard manual work all his life without any ill effects.

Maidstone. HUGH G. MITCHELL, M.B., B.S., D.L.O.

HERPES OPHTHALMICUS FOLLOWING CHOREA AND ASSOCIATED WITH VARICELLA.

THE following histories are rather difficult of interpretation.

A healthy-looking girl, aged 7, was admitted on December 9th, 1929, with a history of "jumpiness" for six days. Her well-marked chorea was treated with large initial doses of liquor arsenicalis, which were gradually decreased. By December 28th she had taken 424 minims, and her movements had almost stopped. On January 4th, twenty-six days after admission, she developed herpes in the distribution of the upper division of the left fifth cranial nerve, the cornea escaping. The herpes was confidently diagnosed as being due to arsenical poisoning of the fifth ganglion, a well-known arsenical symptom, though uncommon in the treatment of chorea, and also rare as the site of shingles in the child. However, in the same ward, three days later, a girl, aged 5, with acute suppurative pneumococcal arthritis of the left hip, developed chicken-pox, thirty days after admission.

Ought this second event to throw any doubt on the diagnosis of the cause of the fifth nerve herpes? There have been no further cases of herpes or chicken-pox. The patient with chicken-pox was isolated at once; twelve other patients had not had chicken-pox, and three patients had had chicken-pox. The bias of the writer's view is betrayed, for the girl with herpes ophthalmicus was not isolated.

I must thank the medical superintendent of the West Middlesex Hospital for permission to publish these cases.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

FINCHLEY DIVISION.

A LECTURE was delivered before the Finchley Division of the British Medical Association, on March 18th, by Dr. WILFRED SHELDON, who took as his subject "Rheumatism in childhood"; he dealt with the conduct of rheumatic clinics, as well as with the pathology and treatment of this and related disease.

Rheumatism in Childhood.

Dr. Sheldon remarked that there were already at least ten rheumatic clinics in London, as well as a few in the larger provincial cities, but little uniformity was evident in the procedure adopted. This variety of method facilitated the free development of each clinic, enabling it to utilize effectively the experience of others. Much of the value depended on the detection and treatment of the early mild cases in which the diagnosis of rheumatism was suspected rather than confirmed. The clinic should, however, be able to deal with the disease in all its manifestations, and should accept children with established heart disease and others who had chorea. Home visits were paid by the staffs, and environmental defects were corrected whenever possible. Close co-operation was encouraged between the clinics and the school medical service, and it was mentioned that out of 266 children at the rheumatic clinic at the Great Ormond Street Hospital, 45 (1 in 6) were attending special clinics for the physically defective. The general practitioner could use these rheumatic clinics for the supervision of children convalescent from active rheumatic disease. Such a clinic required the resources of a hospital at its disposal, and the lecturer outlined the way in which co-operation between the two institutions could proceed success-fully.

A report was then given of the work in the rheumatic clinic at Great Ormond Street Hospital. During the last two years an analysis had been made of 600 con-secutive cases, the conditions encountered being classifiable in four groups: rheumatic pains in the limbs (235 cases); a previous history of rheumatic fever or acute articular rheumatism (133); chorea (197); and rheumatic heart disease (266). The lecturer discussed these four groups in detail, and showed a chart indicating that the incidence of rheumatic pains bore some relation to the prevalence of cold and wet weather. Treatment was outlined, and it was mentioned that in cases with rheumatic pains sodium salicylate was often disappointing, though it had proved of great service in acute articular rheumatism. The external application of the liniment of methyl salicylate had been more effective, but the general health required attention, and such a tonic as a mixture of equal parts of malt and the syrup of iron iodide was valuable. Dr. Sheldon commented on the inability of patients suffering from any form of rheumatic infection to establish a lasting immunity after the attack. As regards the sequels of rheumatic fever, 93 out of 133 cases showed evidence of cardiac involvement, chorea followed in 5 cases, and pains in the limbs in 12. Only 23 children had been entirely free from rheumatic symptoms since an attack of rheumatic fever. Such figures indicated the necessity of keeping under observation for some time children who had once had rheumatic fever, and such supervision was one of the functions of the rheumatic clinic. Discussing chorea, the lecturer stated that of 197 cases of this disease, rheumatic heart disease had occurred in 52; rheumatic fever preceded 5 cases, and in 15 instances rheumatic pains in the limbs accompanied or followed it. Thus, 36 per cent. of the children with chorea had also other forms of rheumatism. There were, however, probably other factors than rheumatic infection in the production of chorea, and the sex, psychical shock, and mental stress were important. Rheumatic heart disease was found in 265 of the 600 children examined. In 36 instances its on-set was insidious, and when this was the case it tended to run a slowly progressive course, resisting therapeutic measures. An account was given of the salient points in early diagnosis, and of the production of cardiac murmurs. A chart was exhibited to illustrate changes in the mitral murmurs in 232 children during a period of a year or two. In 21 cases the murmur was proceeding to mitral stenosis, in 42 a diastolic murmur had disappeared, while in 140 there was no alteration; in 25 cases in the series the heart became normal. Figures were reported showing that in approximately one-third of the cases of rheumatic infection had developed after the symptoms of rheumatic pains, chorea, and rheumatic fever tonsils had been removed. Of 105 children with rheumatic pains in the limbs before tonsillectomy, the pains continued in 50 per cent. subsequently, while in 20 out of 95 children pre-existent chorea was unaffected by this operation. Dr. Sheldon remarked that, unless it could be shown that tonsillectomy had a definite influence in the prevention of cardiac disease, there seemed to be small justification for it merely on the ground that the child was a rheumatic subject. It seemed more probable that its value in rheumatic children was related to the degree of impairment of the general health attributable to the tonsils. In other words, tonsils should not be removed unless there was evidence that they were affecting adversely the general health. Such evidence as a history of repeated sore throat, chronic enlargement of the tonsillar glands in the neck, and the appearance of the tonsils must be taken into consideration. Their size alone was an unreliable guide, small scarred tonsils being often as injurious to the child's health as when these organs were hypertrophied.

Reports of Societies.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of the Aberdeen Medico-Chirurgical Society on April 3rd, with the vice-president, Dr. HENRY PETERKIN, in the chair, Mr. ANDREW FOWLER demonstrated two patients to show the after-results of operation for diastasis of the femur and habitual dislocation of the patella.

The first patient, a boy aged 9, had sustained an injury to his right leg in November, 1922. When admitted to hospital a month later he was found to have a diastasis of the lower end of the femur, with displacement of the epiphysis forwards and fairly firm union of the fragments in this position. At an operation in December, 1922, part of the upper fragment was removed through an external incision by chisel, and the epiphysis was levered into position. The limb was then put up in plaster flexed to a right angle, and the child was now able to walk perfectly. There was no shortening, and no deformity apart from slight genu valgum. No damage had been done to the growing end of the bone by removing a thin layer from the diaphysis.

In the second case a girl aged 12, the patella had been dislocated laterally by a fall at gymnastics five years previously. There had been frequent dislocation subsequently, and before operation the patella was found to slip over the external condyle of the femur on flexion of the knee. A marked degree of arthritis was present, with much grating. Operation was indicated on account of disability and increasing arthritis. An incision was made from two inches above the external condyle of the femur to a similar distance below the tibial tubercle, and the attachment of the ligamentum patellæ was chiselled off and the fragment was turned to a stripped area on the tibia immediately quarters of an inch internal to the original insertion of the tendon. A wedge graft was taken from the tibia and inserted into the external condyle, which was also vertical. The limb was put up in plaster at right angles. The knee was flexed. Movements were commenced six weeks after the operation, and the final result was excellent.

Dr. H. ROSS SOUTER gave the history of a case of epithelioma of the epiglottis, and demonstrated the condition after removal, in a male patient, aged 62, who had been first seen in August, 1923, complaining of discomfort in the throat for the previous two months. Examination at this time had revealed no abnormality except a string of muco-pus on the epiglottis, but a month later irregularity of the margin of the epiglottis had developed. There were

no enlarged glands, and the Wassermann reaction was negative. A section was removed for microscopical examination, and the condition was reported to be epithelioma. Low tracheotomy was performed, and the epiglottis was excised by diathermy knife and scissors. The patient had been seen at intervals since. The stump of the epiglottis was healthy, and there was no recurrence elsewhere.

Dr. Souper also described the features of a case of aspiration of a foreign body. The patient gave a definite history of having aspirated the single pip of a "seedless" orange twenty-four hours previously. There was discomfort on the right side of the chest and an asthmatoid wheeze, audible over the middle and lower lobes of the right lung. The patient was prepared for operation with atropine and morphine, and bronchoscopy was performed under chloroform and oxygen anaesthesia twenty-six hours after the aspiration. The foreign body was seen in a secondary bronchus of the right lower lobe, surrounded by pus and acutely inflamed mucous membrane. It was seized by a forward grasping forceps, and was removed with the bronchoscopy tube. There were no sequels. The points of note in the case were the very definite history of aspiration and the early onset of local inflammatory reaction. If removal had been unsuccessful, obstructive emphysema of the lower lobe would have developed, followed by obstructive atelectasis.

Dr. J. T. FRASER showed a breast removed for Paget's disease, and discussed the history of a case of renal glycosuria followed by diabetes mellitus.

GENETICS AND LIVE-STOCK IMPROVEMENT.

AT a meeting of the Royal Society of Arts, on April 9th, with Sir DANIEL HALL, F.R.S., in the chair, Professor F. A. E. CREW read a paper on genetical methods of live-stock improvement.

Never in the history of agriculture in this country, said the speaker, had the economics of breeding demanded more careful consideration than now. Costs of production were high and returns were low; arable farming was largely being replaced by grazing in order to reduce losses; sheep markets might at any time become saturated; the marketing of cereals would probably remain as unprofitable as it was at present. At this period of agricultural depression the only sound policy for the British farmer was increased live-stock production and the marketing of crops in the form of animal commodities, since, owing to the tastes of the British public, fresh animal products could not at present be affected by foreign competition. If, then, the aim of the agriculturist was to be the production of standardized and uniform animal commodities, it was necessary to consider the benefits that might be conferred upon live-stock breeding practice by the science of genetics. Discoveries in this field of knowledge had made the breeder largely dependent on information that could not be acquired on the farm, so much so that the actual value of any system of breeding could be assessed only by one versed in genetical science. On the other hand, that science could help the breeder only if he knew already the primary business of farming, had studied his policy, and had defined what he wished to produce.

The Standard of Excellence.

A definition of what the breeder wished to produce led to the construction of standards of excellence, and thus to serious difficulty. The ideal animal was one that could live, thrive, and reproduce in a particular environment as well as produce certain animal commodities. Difficulties in the way of making standards were the complex general economics of production, the inconsistency of standards, since it might be impossible to obtain in a single animal all the desired points of excellence, and the fact that the standards for males and females might be quite different. Too commonly the standards were set not by the breeder, but by the buyer, who knew little, if anything, of breeding - for example, the manufacturer of textile goods apparently regarded the sheep as a vehicle of fleece adaptable to commercial purposes; to the breeder the fleece was a protecting covering which would help his sheep to thrive, for he had to consider fertility, milk yield, and growth rate in relation to the system of husbandry and the conditions of his farm. The ideal type, then, was that which so harmonized with the conditions of husbandry that it achieved the fullest expression of its hereditary endowment, and so adequately fulfilled the destiny for which it was intended. Exact information about this destiny and habitat was necessary before any standard of excellence could be intelligently constructed.

Breeding an Ideal Type.

Breeding was a synthetic operation, but before there could be intelligent controlled synthesis there had to be analysis. Animal breeding demanded the scientific analysis of excellence, and the study of the interrelation and mode of inheritance of the various characters which in their combination constituted the ideal. It was important to recognize that the majority of the component characters in any ideal type were Mendelian dominants, and the majority of undesirable characters were recessives. It was therefore not to be expected that a mating would produce progeny of the desired standard unless the parents approached that standard; nor was it uncommon for good parents to throw bad offspring. Any culling had to be carried out as a national scheme, since the herd or flock was too small a unit when uniformity of produce was sought. Inbreeding gave such diverse results because it was the quickest means of disclosing the hidden recessives. The only sure way of improving the live stock of a country was by improving the education of the stock breeder, and by offering rewards for ability. Shows had lost much of their importance, for in them too great stress was laid on standards which had no relation to economic worthiness. The fact that pedigree was an inadequate instrument for assessing worth was not clearly recognized, and the prize was too often given to the best looker and not to the best performer. The milk-recording schemes, the pig-testing station, the wool yield test, the laying trial, and so forth, were the instruments contributing to the education of the stock breeder and the means by which he might gain adequate rewards for vision and ability. The State should take a part in building up an improved stock by the control of all sires. The general level of excellence of the commercial stock of this country was pitifully low, and there was an urgent need for breeding pedigree stock according to a genetically approved system, to grade up commercial stocks by means of pedigree sires, and to produce first crosses for certain commercial purposes by the use of two pure-bred stocks. Moreover, there was reason to believe that about 50 per cent. of infertile matings were due to genetic causes, and it was the soundest of policies to breed for fertility as well as for other qualities of economic worth. The need for improving quality and lowering the cost of production could be met by breeding for increased productivity and quality. For market production it was necessary to discard low producers and their progeny; thus, it was not generally recognized that a 1,000 gallon cow was as profitable to her owner as five 650 gallon cows. The use of a cow beef type sire for the unwanted calf of the dairy cow would bring about improvement in beef production.

The Future.

Some of the investigations which had to be carried out by breeders and geneticists working in harmonious collaboration were the definition of standards, the analysis of excellence, the purification of stocks, and the removal of the menace of sterility. At present the ideal type could be obtained only by the slow process of selective breeding, but there were indications that endocrinology might play an important part in the future. The growth of an animal might be controlled by injections of one endocrine product; fertility, fat deposition, lactation, and so forth, by others; and men would be able to control his live stock more completely and more quickly than was ever deemed possible.

Reviews.

TUBERCULOSIS IN CHILDHOOD.

TUBERCULOSIS in Childhood,[1] edited by ENGEL and PIRQUET, is entitled a handbook; it is actually a large volume (vol. i) of nearly 900 pages, with 481 illustrations. It is an important contribution to an important subject, and one which is worthy of German medicine and German printing. Pirquet's lamented death early last year was a serious loss to the book, but his place as co-editor has been ably filled by Dr. Priesel of Vienna; among the thirty odd contributors are names well known over Europe. Lord Dr. Stanley Griffith of Cambridge writes with special authority on the types of tubercle bacilli found in human lesions in Great Britain and elsewhere. The subject is one of vast extent owing to the complexity and variety of tuberculous lesions in childhood, and of very great importance; in the last twenty years there have been several really important advances in diagnostic methods with corresponding advance in knowledge of general pathology. The discovery of a safe and convenient diagnostic test by Pirquet in 1907, the investigations in morbid anatomy by Albrecht, Ghon and Kudlich, and others, with regard to the primary focus in the lung and the so-called "primary complex" of the focus with its associated glandular enlargement, and the perfection of x-ray photography of the chest, have all taken place in this period. The purpose of this book is to review, appraise, and consolidate these various additions to knowledge.

The material in the first volume falls into two main sections—pathological and clinical—although in the clinical section it is hard to prevent pathology from breaking through. In the first section one important chapter is devoted to the portals of entrance; and the result of large and carefully compiled post-mortem statistics in Vienna and elsewhere is to give the lung an overwhelming priority as the first site of lodgement of tuberculous infection. It is claimed, further, that these post-mortem findings are now being corroborated by an ever-increasing number of cases where not only tuberculous root glands but the primary lung focus itself can be seen in x-ray films. Another long and beautifully illustrated chapter is section deals with morbid anatomy, not only in the lungs and respiratory tract, but in all parts of the body. The remaining two-thirds of the book are occupied with the clinical types of the disease and their clinical features, diagnosis, and treatment. The greater part of this section is devoted to pulmonary tuberculosis, divided into three stages—primary, secondary, and tertiary. General tuberculosis and tuberculous meningitis are regarded as terminal phases of the secondary stage; while tertiary disease covers the examples of chronic phthisis, nearly all of which are found in later childhood and in adolescence. But a full description follows of tuberculosis of the skin, of the pleura and peritoneum, of the bones and joints, eyes, and ears, and there is a final chapter on the so-called parathe tuberculous lesions, erythema nodosum, phlyctenular conjunctivitis, scrofula, etc.

This catalogue of contents only indicates the encyclopædic character of the volume, which is apparently to be followed by another. The survey of this great subject has been well planned by eminent editors, and the contributors are masters of the subjects they deal with; the illustrations are excellent, and almost embarrassing in their number. The book is of great value as a complete book of reference, and as an authoritative account of the present state of knowledge of tuberculosis in childhood in all its forms.

PRACTICAL UROLOGY.

IN his Practical Urology[2] Dr. P. BAZY has rewritten and amplified a contribution made some years ago to the "Encyclopédie scientifique des aide-mémoire," on the subject of di-eases of the urinary system. It is written primarily for the general practitioner. He points out in his preface that di-eases of the urinary tract frequently demand urgent treatment, and that the practitioner may be called upon at short notice to deal with such a painful condition as retention. He requires, therefore, a manual in which he can look up at a moment's notice the treatment best calculated to relieve his patient. This information is supplied within the covers of *Urologie Pratique*, and in order that there may be no difficulty in finding it, much attention has been given to the alphabetical index. The work is divided into four parts—the first dealing with methods of examination, the second with treatment, the third with symptoms, and the fourth with troubles of micturition. The text is clearly written, and the information given is precise and practical. The aim of the author is excellent and has been in great part achieved, but after reading his book we are assailed with the usual doubts whether it is within the capacity of any busy practitioner to absorb the amount of knowledge that is provided for him by writers on special branches of medicine. Such publications as *Urologie Pratique* will be used primarily as works to be referred to in times of difficulty rather than as books to be read from cover to cover.

GROWTH AND MOVEMENT OF PLANTS.

SIR J. C. BOSE's work on the *Motor Mechanism of Plants*, which was reviewed in our issue of July 13th, 1929, has been followed by an equally interesting work on the *Growth and Tropic Movements of Plants*.[3] As in the previous work, one cannot but admire the delicacy of the author's experimental methods, which have enabled him, for example, to measure the amount of growth exhibited by a plant in the course of a few seconds. The new book is a veritable budget of fresh facts and new ideas. In regard both to the elementary phenomena of growth and to the modifications of its direction under varying conditions, which are included under the term "tropisms," the author has established the fact that, whatever stimulus may be applied, the nature of the response is invariable. It has hitherto been supposed that plants exhibit specific irritabilities; it is now shown that whether the stimulus be that of gravity, radiation within or beyond the visible spectrum, electricity or mechanical irritation, there is but one irritability of the growing organism, which responds to all in essentially the same manner. This is the main general conclusion of the author's work; but special points of interest, too numerous to mention, are to be found scattered through the book. For example, proof has been given that in the upward bending of plants under the influence of gravity, the force is exerted from above down on the upper concave aspect of the stem; and by means of a fine electric probe the sensitive layer which brings about the change of direction has been identified as that composed of statocysts or cells containing large starch grains. These observations support the theory that the weight of the starch grains is the stimulus to the geotropism. Very suggestive, also, is the incidental observation that certain cells become specially adapted for the transmission of light stimuli, by acquiring the shape of a lens.

In his preface the author justly remarks that preconceived bias has to yield to unimpeachable fact. Growth being associated, in the mind of a pathologist, with cell proliferation, one would suppose that under constant and uniform conditions cell proliferation would proceed uniformly, and the resulting increase would be represented by a straight line. The author has shown, however, that this is not so in the case of plants. The increase here is rhythmical: there is first a somewhat rapid elongation, slowing down at the acme and terminating in a partial return towards the original length. There appear, therefore, to be two phases—an elongation alternating with a shortening, the former being the greater, with an increase in length as the net result. Doubtless the author will in due time turn his attention to the conditions influencing cell proliferation, with results, let us hope, which may assist the pathologist in unravelling the subtleties of tumour formation.

DENTAL HISTOLOGY AND EMBRYOLOGY.

UNDER the title *Dental Histology and Embryology*[4] Dr. B. ORBAN, now professor of dental histology and pathology in the Chicago College of Dental Surgery, presents the results of his investigations into the nature of the dental tissues. Much of the work was done in the histological laboratory of the Dental School of the University of Vienna, and the author pays a kindly compliment to its director, Dr. Gottlieb, in the dedication of his book. In the preface criticism is invited—"for it is only through criticism that real constructive work can develop." The statement that well-developed enamel contains 3 per cent. organic substances; the conception of an enamel cuticle which is not keratinous and is destroyed by acids; the idea that the dentinal fibrils entirely fill the dentinal canaliculi; the importance ascribed to cementum as a controller of dentine calcification, and as governing the existence of alveolar bone; the omission of any reference to "sepsis" as a cause of cement hyperplasia (which is described as "a favourable reaction to irritation") or as a cause of destruction of alveolar bone (the distinction is ascribed to disuse, or to "physiological wandering of teeth")—these and other points will evoke criticism, but we think the author may be relied on to turn to good account the observations of his critics. For our part we are especially impressed by the photomicrographs showing removal of destroyed cementum, and by the method of constructing models of developing teeth, and in general by the excellence of the sections chosen to illustrate the work; dental sections are the most difficult of all to prepare. The book is a valuable addition to dental science.

NOTES ON BOOKS.

PROFESSOR R. D. RUDOLF'S *Notes on the Medical Treatment of Disease, for Students and Young Practitioners of Medicine*[5] has now deservedly reached a third edition. The previous issues in 1921 and 1923 were reviewed in our columns (1921, ii, 44; 1924, i, 327). The difficult task of keeping the text from considerable expansion while adding what is necessary about recent advances has been very successfully solved. Minot and Murphy's liver treatment of pernicious anaemia is, of course, given, and with the comment that, though it is premature to state that the disease can thus be cured, as long as the treatment is continued the blood usually keeps about the normal and the dreaded crises do not occur. In the account of Jennerian vaccination the importance of its performance in infancy is insisted upon, as the rare cases of post-vaccinal encephalitis practically all occur after primary vaccination done during the period of school life or later. The book reads easily, and conveys the fruits of long experience in clinical medicine.

DR. HUBERT HIGGINS, in his *Biological Reversion and Hippocratic Anatomy*,[6] asserts that the results obtained by osteopaths have never been satisfactorily explained by their critics. There should, however, in his opinion, be no difficulty for those who understand Hippocratic anatomy. For example, the morbid anatomy of lymph stasis of the spinal canal is, according to the author, perfectly obvious in the living, though obscure in the dead, body. "There is," he considers, "an intrinsic cellular expansion, an active hypertonicity of the connective tissue inside the vertebral canal, which, being resisted by its rigidities, exercises pressure on its contents, and also on the nerves issuing from the intervertebral foramina. The dorsal interlaminar ligaments bulge, causing definite ridges of elastic resistance, which may be exceedingly difficult to overcome. Forcible separation of the dorsal vertebrae, by bending the dorsal curve backwards over the knee, will, in suitable cases, immediately diminish, or even temporarily abolish, this abnormal intravertebral resistance." One may be excused for mistaking this for pure osteopathy.

DR. A. J. CHURY'S little monograph on diphtheria,[7] which appears to be a reprint from *Bratislavské Lékárske Listy*, is divided into four parts, devoted respectively to the epidemiology, clinical aspects, occurrence of acetonaemia in diphtheria, and active immunization. For the benefit of those not familiar with the Czech language, to whom a bibliography of 219 references may also be of use, summaries of the third part in French, English, and German are appended.

The Rev. H. G. G. HERKLOTS has gathered together a short series of *Hospital Sketches*,[8] written by various members of the Church Missionary Society who are working in Africa and the East. Missionary societies, in linking up hospitals and schools in savage districts to the Church, recall to mind the condition of Europe in the Dark Ages. The little book contains some interesting stories of the difficulties experienced among the savage races of Uganda and Nigeria, and in ancient civilizations such as the Persian and the Chinese. The value of tactful health propaganda is plain in each case.

Under the auspices of the Chadwick Trust courses of popular lectures are given every year in London and other large towns in Great Britain on almost every branch of sanitary science. Two lectures on *Sewage and Sewage Disposal*,[9] delivered last year at the Institution of Mechanical Engineers, have now been published, and can be recommended as a lucid summary of recent progress in this department of public health.

CORRECTION.

In our review of Pottenger's *Symptoms of Visceral Disease* (April 12th, p. 700) it was stated that the price had gone up by 13s. 6d. We learn from the publisher, Mr. Henry Kimpton, that this should be 3s. 6d., as the price of the previous edition was 28s.

[4] *Dental Histology and Embryology.* By B. Orban, M.D. Second edition. Philadelphia: P. Blakiston's Son and Co., Inc. 1929. (Med. 8vo, pp. xviii + 316; 291 figures. 4 dollars.)

PREPARATIONS AND APPLIANCES.

A MODIFIED OGSTON'S INHALER.

DR. JOHN HALTON (Liverpool) writes: I have devised a modification of Ogston's inhaler which consists of: (1) a Schimmelbusch mask (modern type) to which are fixed four sockets; and (2) a wire frame, shaped in the general outline of the mask, having four 4½ in. hinged legs which fold flat. In use the mask is prepared as usual with five to six layers of gauze, the legs of the frame are fitted into the sockets, a towel is wrapped round the frame and pinned into position. Personally, instead of a towel, I use a strip of white lint, roughly 6 in. by 18 in., hemmed at one end to within 1 in. of each of its long sides. One of the legs is passed through this hem before being fitted to the mask, making the fixture more secure.

Ogston's principle is, briefly, that by means of a chamber placed round the mask more effective vaporization takes place, the heavy ether vapour is concentrated and conserved, and it is also warmed to a certain degree by the patient's own expiratory efforts. Thus smaller amounts of ether are necessary, and resultant post-anaesthetic complications are undoubtedly minimized as compared with the ordinary open method. The advantage claimed for this modification is that it folds flat and takes up no room in the anaesthetist's bag. With very little experience one finds that this method is almost ideal for the administration of long or short anaesthesias. For dental extractions, tonsillectomies, and other short operations, using a 1 in 12 to a 1 in 8 C.E. mixture, the mask is kept slightly raised for the first dozen breaths; then, as it is gradually lowered, the concentration can be rapidly increased with no discomfort to the patient. A short, quiet induction is usually obtained, and an anaesthetic period, with the mask removed, of two to five minutes, with recovery in twenty minutes, depending on the time of administration, is easily brought about. For longer operations a change over to pure ether is advisable, but one-half to one third of the usual quantity of the drug only is necessary. A metal dropper—Bellamy Gardner's—is advantageous, as opposed to the usual wick method; it enables ether to be delivered to the mask in all positions.

Messrs. Alexander and Fowler of Pembroke Place, Liverpool, have constructed this apparatus for me, and the accompanying illustration is, I think, self-explanatory.

British Medical Journal.

SATURDAY, APRIL 26TH, 1930.

A GENERAL MEDICAL SERVICE FOR THE NATION.

LAST year the Representative Body of the British Medical Association approved the report of the Council on encroachments on the sphere of private practice through the activities of local authorities and certain voluntary agencies. To many members it seemed that, valuable though this report was, the Association had still to formulate constructive proposals demonstrating how national provision for the medical care of all classes of persons might be made on lines acceptable to the profession. Indeed, at the same meeting of the Representative Body such action was, in fact, taken in a limited sphere by the adoption of the Association's National Maternity Service Scheme for England and Wales. That scheme was very well received by the interested public, and has already influenced the development of thought and of practical proposals in the matter with which it deals.

Since the autumn the Council of the Association, through a strong and representative committee, has been considering the medical service requirements of the nation in their wider aspects, and has now approved, and is submitting for the consideration of the Divisions and of the Representative Body, proposals for a general medical service. These proposals are published in the *Supplement* this week (p. 165). In reading them it is important to bear in mind, first, their derivation from and connexion with the documents already referred to, and the relation to them of the revised Hospital Policy of the Association printed in last week's *Supplement* (p. 151); secondly, that they are based to a very large extent on policies which the Association has already adopted; thirdly, that they are made not as forming a scheme which cannot be varied, but as a contribution, on lines acceptable to the profession, towards a national discussion of the subject; and, fourthly, that they are intended at least as much for the education of the public as for the serious consideration of the medical profession, and have been formulated and set out with this object in view.

The scheme is important and timely. It is becoming more generally recognized that national provision of the kind proposed is desirable, even necessary. Those who are officially responsible for legislation and administration, and those who are unofficially interested in the social services, are beginning to consider, in actual and practical detail, the methods by which such provision may be made. The State has passed beyond the stage, which occupied almost the whole of last century, in which it conceived its duties in regard to public health to be confined to dealing with general sanitation and infectious disease. It has passed beyond the stage, occupying fully the first quarter of the present century, in which it concerned itself also with the treatment of a few special conditions and with limited sections of the community. It now contemplates making complete provision for the medical care of the whole community, or at least of that large proportion which is unable to make such provision for itself. Lack of funds will probably prevent the actual establishment of a comprehensive national scheme during the next few years, but the formulation of such schemes in certain quarters and in accordance with various ideas is even now proceeding apace. These ideas are not all likely to conform with what the medical profession believes to be good, and the British Medical Association should be in the forefront, as it has been in past years, in making proposals whose operation it believes will benefit the public and preserve all that is best in professional traditions and practice. Mr. Greenwood, the Minister of Health, has promised a general survey of the social services: certainly in undertaking this survey he ought to be informed about the lines on which the medical profession would co-operate in making the services more effective in promoting and preserving the health of the nation.

Though in matters of this kind detail is important, it is the general outline of the scheme which should at present be noted. It is based upon attention to the preventive aspects of medicine as well as to its curative aspects; and includes the provision of a family doctor or general medical practitioner for everybody, together with such aid as may be required in the way of consultant, nursing, and other additional or ancillary services. It would provide all except institutional services by means of a national contributory insurance scheme, including on a compulsory basis not only all insured persons as at present defined, but all the dependants of such persons, and, by an ingenious but practical plan, all persons who have hitherto been dealt with by district medical officers under the Poor Law. In addition, it would admit on a voluntary basis all voluntary contributors under the present national health insurance system with their dependants, together with some other persons of modest means who are not now included in the system.

Contributory insurance is of the essence of the scheme; it is offered as an alternative to methods to which the great majority of the medical profession are opposed, and of which the project to create a class of whole-time salaried doctors to do domiciliary work in association with municipal clinics is the extreme example. Institutional care would be provided in another way. The committee which considered the scheme found, reluctantly (as the Royal Commission on National Health Insurance had done), that the difficulties of including this provision within the range of services rendered under a compulsory insurance scheme were insuperable: indeed, the Local Government Act of last year has added to these difficulties. Local authorities would continue to provide hospital accommodation for the community generally as supplementary to the provision made by the voluntary hospitals and the insurance scheme. It would be open to individuals to provide, by a voluntary insurance arrangement or a hospital contributory scheme, for payment required under Section 16 of the Local Government Act, 1929, or otherwise from the recipient of the hospital benefit; and of course it would still be possible for approved societies to provide for such payments by their members through an additional cash benefit. It should be noted, too, that there is contemplated an extension of hospital accommodation, in particular of the kind which has been designated, for want of a more exactly descriptive term, the "home hospital," in which the institutional provision would be efficient yet not very expensive, and where the patient, while remaining under the responsible care of his or her own family doctor, would be in more or less close connexion with the larger general hospital. These and other important features of the

scheme, however, can be appreciated only by a more detailed study of the proposed arrangements.

The discussion to which the proposals will give rise, both within the medical profession and among the public, must, if it is to be useful and effective, proceed upon the basis of a perusal of the whole document. It is a serious and very valuable contribution to the subject with which it deals, and we believe that a critical examination will show that it is only along lines such as those indicated that real progress in national health provision and administration can ultimately be made.

ROBERT BRIDGES.

IT is so long since the Poet Laureate retired from the practice of the medical profession that many members of it may have been surprised to learn from the obituary notices this week that he was a graduate in medicine; and only the veterans among us will recall the time, now fifty years ago, when he was a member of the staffs of the Great Northern Hospital and the Hospital for Sick Children, and was actively engaged in carrying out the strenuous duties of a casualty physician at St. Bartholomew's Hospital. Not only did he do so, but he contributed to the pages of the *St. Bartholomew's Hospital Reports* an interesting account of the casualty department and some most useful reflections upon its value. Dr. Bridges's experience led him to hold strong views decidedly unfavourable to indiscriminate out-patients and casualty relief, most of which he felt would be more properly and more efficiently given by general practitioners than by hospital physicians working under the conditions he described. This was not his first contribution to the *Reports*, for in 1876 he had written a suggestive paper on "A severe case of rheumatic fever treated successfully by splints." The patient was being exhausted by severe and constant pain, which yielded to no drugs, and the remission of pain, secured by applying splints to the limbs so as to prevent movement, no doubt had considerable influence on the progress of the case. Nearly half a century later his pen turned again for a moment to a subject related to medical science, when he collaborated with Dr. Cuthbert Morton in a tract on the language of anatomy—a brilliant attempt to bring order out of the terminological chaos into which British anatomy had been plunged.

Robert Bridges's first volume of verse appeared in 1873, and his last and greatest philosophical poem, *The Testament of Beauty*, was published six months ago, on his eighty-fifth birthday. Before his connexion with the practice of medicine came to an end his classical humour had found outlet in the production of a Latin elegiac poem of 558 lines,[1] in which he celebrated the history of the foundation of St. Bartholomew's Hospital and lightly treated of the members of the staff. Not long after the publication of this poem he retired, in 1882, from medical practice and gave himself up wholly to literature. His fame as a poet grew slowly, almost by stealth. Robert Bridges was a writer deeply versed in all the lore of metre and of prosody, with a mind alive to the scientific side of his art without losing the true poetic touch. He has been acceptable to critics of his own age as well as to the young poets of this century to an extent that is really remarkable. The volume *October and Other Poems*, published in 1920, included a number of war poems, some of which had been published anonymously. Those critics who agreed with a certain member of Parliament in asking that the Poet Laureate should be officially desired to "earn his butt of sack" must have been astonished when they found that the spirited ballad "Der Tag," which appeared in the *Times*, was from his pen, as well as other war ballads.

The medical profession may well feel proud that its only Poet Laureate (unlike so many of his predecessors in that office) was a great poet and a fine scholar, and that the years he spent in medicine were a vital contribution to Robert Bridges's training for the life of letters.

[1] Thomas Fletcham Roberti Bridges de Nosocomii Sancti Bartholomaei Londinensis. In quo narratur Historia Fundationis Nosocomii, Illustres ibi viri qui olim versati sunt, Laudini: *Imprimis* Hodiernus Status ejusdem Nosocomii, in cujus officina exemplaria mundentur.

SHAKESPEAREAN MEDICINE.

INTEREST in what Shakespeare knew and said about the medicine of his day has led some to read into his references to the subject a more profound or prophetic knowledge—for example of the circulation—than there are solid grounds for accepting, and his representations of contemporary men, such as his Dr. Caius, have also excited some justifiable comment. It is therefore useful to have at hand a survey of *Medicine in the Days of Shakespeare*,[1] especially when it is so attractively drawn as that which the students of arts and science at University College were fortunate enough to have presented to them in November last by Dr. Herbert R. Spencer. The lecturer is a former president of the Medical Society of London, which possessed the valuable manuscript diaries of the Rev. John Ward, vicar of Stratford-on-Avon (1662–81). Whether there is anything more than an accidental coincidence, or whether some unconscious inspiration or suggestion may have been at work, it would (to borrow the opening phrase of an otherwise mute essay writer) "be otiose to enquire"; but it so happens that two other former presidents of that same society—Sir Charles Ballance, on an occasion more years ago than need be insisted on, and Sir StClair Thomson in the Society's Annual Oration for 1915—made exhaustive collections of quotations bearing on the healing art from the Shakespearean Corpus. Dr. Herbert Spencer not only gives a broad survey of medicine in Shakespeare's time, derived from wide reading rather than from the poet's writings, but incidentally compares it with present-day conditions. Three centuries ago the healing art was one and undivided, now it is a mosaic of specialties, though this is a comparatively recent change; for, as he shows by quotations from some of his former colleagues, fifty years ago the then budding specialism was decried as a foolish and short-lived phase, a dictum synchronous with that previously, and indeed quite recently repeated, that surgery had reached finality. The physicians in Shakespeare's time paid much attention to dietetics, and Queen Elizabeth once listened patiently for five hours to a dissertation by her physician, Walter Bailey, on the questions whether slowly digested foods were preferable to those easily digested, and whether life could be prolonged by medical art. The physicians were dignified scholars with a much better position than the surgeons and the apothecaries, the latter being described by William Bullein as the physicians' "cookes." There was a curious contrast between William Harvey, who was content with prescribing a simple pill of gamboge and left £20,000, and Sir Theodore de Mayerne, who used a pill with thirty-six ingredients and left a fortune of £140,000. The status of the apothecaries, who gradually developed from the spicers, pepperers, and grocers, was greatly improved when in 1617, largely through the influence of Sir Theodore de Mayerne and Gideon de Laune, the Huguenot apothecary to Queen Anne, they were granted a separate charter constituting them a city company as the Society of Apothecaries of the City

[1] London. 1929. John Bale, Sons and Danielsson. (Pp. 27, 2s. 6d.)

of London. Although the surgeons of the time usually came of a humbler social class and received a less liberal education than the physicians, they based their practice on sound anatomical lines and were rapidly improving their position in the medical world; they not unnaturally resented the action of the physicians, some of whom also practised surgery, in prohibiting them from giving internal remedies. Ambroise Paré, who wrote treatises on medicine and midwifery, is regarded by Dr. Herbert Spencer as "the reformer of surgery and midwifery."

PULMONARY ASBESTOSIS.

DR. E. R. A. MEREWETHER and Mr. C. W. Price have carried out with commendable success an official inquiry into the effects of asbestos dust in inducing fibrosis of the lung. Their results are embodied in a report submitted by the Chief Inspector of Factories to the Home Secretary on March 17th, and laid before Parliament on March 24th. Before February, 1928, when a case of non-tuberculous fibrosis of the lungs was discovered in an asbestos worker (Seiler's case), the Factory Department of the Home Office had knowledge of only two deaths about which there was an expert opinion that the inhalation of asbestos dust had contributed to, if not caused, the fatal outcome. In the first of these, described by Dr. Montague Murray in 1906 before the Departmental Committee on Compensation for Industrial Diseases, the post-mortem examination confirmed the clinical diagnosis of extensive non-tuberculous pulmonary fibrosis; in the second, which was described by Dr. W. E. Cooke, director of the Pathological Department of the Wigan Infirmary, in the *British Medical Journal* of July 26th, 1924 (p. 147), the illness showed a progressive dust fibrosis together with chronic tuberculous infection, but the evidence for an etiological relation between inhalation of asbestos dust and fibrosis of the lung would have been stronger if tuberculosis had been absent. The inquiry by Dr. Merewether and Mr. Price was initiated when, investigation of Seiler's case having definitely excluded other industrial and infective causes of fibrosis, it became necessary to decide whether the supervention of this disease in an asbestos worker was an exceptional occurrence or evidence of a grave industrial risk. Dr. Cooke's observation that microscopical examination of sections made from the lung of his case revealed the presence of curious annular and club-shaped bodies, and clinical and pathological observations that have since then been published from Leeds, London, and South Africa, have shown that free silica cannot be regarded as the only dust capable of producing pulmonary fibrosis, and that the inhalation of silicate of magnesium, the constituent of asbestos dust, is, if anything, more effective in producing a like condition. Dr. Merewether and Mr. Price at the beginning of their investigation tried to discover how many persons in the country are constantly exposed in the course of their daily work to the influence of pure or almost pure asbestos dust. Such information was necessary in order that they might check the adequacy of the sample of workers examined, and envisage in proper perspective the problem confronting the industry. The number of exposed workers they believe to be about 2,200, and of these they examined 363, in 133 the examination including radiology of the chest. Diffuse pulmonary fibrosis attributable to the inhalation of dust was found to be present in 95 of the workers examined, representing 26.2 per cent. of the series. By distributing the workers according to the process in which each had been longest employed, and grouping similar processes together, the authors of the report were able to make certain broad generalizations about the relative effects of work in different dust concentrations. Correlating dust counts with the history and the medical and radiological features of each case, they found that the two factors of greatest importance in the development of fibrosis were length of exposure and dust concentration. Age and sex played no part. While no definite case of fibrosis clearly due to asbestos dust was found among workers with less than five years' exposure, the authors are not prepared to rule out the possibility that such cases might occur on exposure of workers to high concentrations of dust. They lay stress on the fact that for the production of generalized fibrosis a definite minimal quantity of dust must be inhaled, and that the lower the concentration the lower will be the time that elapses before fibrosis develops. If, as seems probable, this view is correct, the practical inferences are very important, for it follows that the application of measures resulting in a reduction of the concentration of dust in the neighbourhood of asbestos processes will bring about, first, a great increase in the latent period preceding the development of disabling fibrosis, and secondly, as measures for the prevention of dust are perfected, the almost total disappearance of the disease. The increased liability of silicotics to pulmonary tuberculosis does not appear to be shared by asbestos workers as a class, or even by those of them who have developed pulmonary fibrosis. In this respect, and in the mode of distribution of the fibrous tissue in the lungs and in the radiological findings, pulmonary fibrosis among asbestos workers differs from silicosis. At the same time as the report by Dr. Merewether and Mr. Price was issued Earl Russell introduced a bill in the House of Lords to extend Section 47 of the Workmen's Compensation Act, 1925 (relating to silicosis schemes), to industries involving exposure to asbestos dust, and to amend the provision concerned with medical arrangements and examinations. In our issue of March 23rd, 1929 (p. 562), we drew attention to inconsistencies in the four existing schemes applicable to groups of "dusty occupations"; this bill aims at making a general scheme to cover all industries and processes to which compensation schemes apply.

DELAYED LETHAL EFFECT OF RADIUM ON TISSUE CULTURES.

A FURTHER step in the investigation of the destructive influence of radium on certain types of new growth is reported by Dr. F. G. Spear.[1] In the *Journal* of September 14th last (p. 503) we referred to the discovery by Dr. Canti and Spear that after a short exposure of a tissue culture to gamma irradiation there was a marked fall in the number of cells in mitosis (40 per cent. that of controls), and that this was followed by an increase (160 per cent. that of controls), which compensated almost exactly for the diminution seen during the first period and subsequent to irradiation. Dr. Spear now reports experiments showing that the gamma rays have a delayed lethal effect on tissue cultures *in vitro*. While the resistance of individual cultures to irradiation was found to vary considerably, it seemed to be established that the greater the intensity of irradiation the sooner the lethal effect could be observed. When 300 mg. of radium was used at a distance of 0.5 cm. the probable life of a culture was approximately doubled if the duration of exposure was halved; with 100 mg. of radium, however, halving the exposure had a less pronounced tendency to double the life of the culture. Comparison of the action of the two doses of radium showed that the exposure of a culture to 300 mg. of radium for six hours produced a lethal effect six days (three subcultures) earlier than did exposure to 100 mg. radium for eighteen hours, though in each case the dosage was the same, amounting to 1,800 milligram hours. It was also found

[1] Report on Effects of Asbestos Dust on the Lungs and Dust Suppression in the Asbestos Industry. By E. R. A. Merewether, M.D., and C. W. Price. H.M. Stationery Office. 1930. (1s. 2d. net.)

[1] *Proceedings of the Royal Society*, B, vol. 106, 1930, p. 44.

that in each series of experiments one or two tissue cultures survived doses of 900 mg. hours and eventually recovered. It appears, then, that the delayed lethal effect following exposure to radium occurs sooner in cultures receiving greater intensity of irradiation for the shorter time.

NOISE IN HOSPITALS.

IT has been said, though doubtless with some exaggeration, that once a man living in a large city has retired for the night he has no alternative before him except to shut the windows and die of suffocation, or to keep them open and be driven mad by noise. Perhaps herein lies an explanation of the fact that though most of us survive, at least for a time, we are all, as everybody knows, mad on at least one point, even if it is only on fresh air. The problem of protecting the hospital patient, who needs both fresh air and silence and cannot be fobbed off with one without the other, has become more difficult than ever since the adoption of the modern fireproof type of construction, involving the use of rigid frameworks of steel, tile, or concrete. According to Dr. Harvey Agnew, who contributes a paper on this subject to the *Canadian Medical Association Journal*,[1] hospitals so built are veritable loud speakers, amplifying every sound and transmitting it to the farthest corners of the building. Reflection from the hard fireproof floors and propagation by the greatly increased plumbing now considered essential to hospital efficiency augment this effect. Architects, says Dr. Agnew, are now paying more attention to special features designed to minimize sound conduction. Stair wells and lift shafts are enclosed and are often placed on a side passage. The long open corridor, stretching from one end of the building to the other, is now broken at frequent intervals by self-closing doors, which help definitely in confining sounds to one unit. Crossbeams help to break sound waves travelling along the ceiling. One architect sets room doors back from the corridor line so as to break conduction along the side walls. As a material for floors, terrazzo is recommended, on account of its cleanliness and durability, though it is undoubtedly noisier than battleship linoleum or rubber. Linoleum admittedly absorbs very little sound and reflects most of the sound waves striking it, but, unlike terrazzo, which amplifies the sound of footsteps, it tends to deaden them. As an insulation against traffic sounds, cinder concrete floor-fill is more effective than ordinary concrete. It is sometimes difficult to minimize sound transmissions from the various service rooms attached to wards, the tendency to-day being to bring these as close as possible to the patients, in order to conserve the nurses' energy; but Dr. Agnew suggests that something might be done by the use of self-closing doors, or by placing these rooms "around the corner." Similarly, conversation and other noises coming from the nurses' room can be reduced by glass enclosures, by care in selecting chart-holders and tables (giving preference to rubber mounts), and by arranging a special rest room for nurses at a suitable distance from the ward. Wall insulation is important, but, even so, enough sound may be transmitted from room to room through non-insulated steam or water pipes to nullify completely the effect of expensive ceiling, wall, and door treatment. Dr. Agnew refers to the recent introduction of a plumbing silencer, designed to eliminate "water hammer." Sounds transmitted through ventilators, he says, may be reduced by covering the openings into the rooms with a "baffle," lined with good sound-absorbing material such as acousti-celotex. All machinery subject to vibration should be mounted on insulated foundations. He describes with some technical detail the treatment of ceiling and wall surfaces with certain synthetic materials designed to prevent sound transmission. Examples are dekoosto, sabinite, akoustolith, acousti-celotex, nashkote, and J-M sanacoustic tile. Hospital authorities who find that they cannot, for financial reasons, undertake the complete reconstruction of their buildings according to the plans and with the materials described by Dr. Agnew may console themselves with the reflection that a good deal of sound can be eliminated at no cost whatever. "Anyone who has required hospital care," writes Dr. Agnew, "knows that one of the most aggravating features from the viewpoint of the patient is the loud conversation, often accompanied with laughter, on the part of nurses and doctors." It is worth considering, too, that the banging of a single door may awaken a dozen patients.

THE PLACE OF THE SOCIAL WORKER.

THE relationship between the voluntary social worker and the education, public health, and public assistance departments of local authorities is a matter of considerable importance, and is likely to become of even greater concern as the last of these departments becomes more intimately associated administratively with the other two. It is somewhat unexpectedly found that it is in the area of the London County Council, the largest of the local government units, that most use has been made of the voluntary worker and that voluntary social organizations have been given the most assured position. The full extent of this work and of this recognition has never yet been comprehensively set forth, and it is peculiarly appropriate that just at this time there should be published an account of the voluntary children's care committee system in London, under the title of *The Private Citizen in Public Social Work*,[1] by Miss Hilda Jennings. The title indicates generally the scope of the volume, and there is a "foreword" by the Hon. Lady Lawrence, chairman of the Special Services Subcommittee of the London County Council, in which she says: "This book is an excellent account of the advantages and difficulties of voluntary work in a sphere in which full responsibility has been accepted by the local authority, and will be read with interest by a wide public who, it is hoped, may be inspired to help in the work." A full and continuing supply of such workers is indeed necessary, not only in London, but throughout the country, unless the sphere of service which they have hitherto occupied with great public advantage is to pass wholly into the hands of public officials in the direct employment of the local authority. Those officials would undoubtedly be quite efficient in performing much of the work, but they would necessarily be working under more strict regulations, and primarily in the interest of the community rather than in that of the individual, and so in a way that may imperil free and varied development. It is true, as Miss Jennings says, that "of late years the distinction between the State and voluntary agencies has been obscured and the social activities of Government departments greatly extended. The volunteer no longer resists the temptation to apply for State aid. There are still many persons who see in this tendency a disquieting sign of social deterioration and of diminished initiative and self-sacrifice on the part of the private citizen. In considering whether this is a true criticism the factors which have influenced the growth of the State as a social agent and the methods by which it exercises its functions must be taken into account. If it can be shown that the individual is more and not less conscious of his social responsibilities, and that the State has ceased to look with contempt on the volunteer, and has commenced to work with and through him, the extension of public responsibility may be a sign of public and private growth rather than of deterioration." This quotation indicates broadly the outlook and the argument of the book. The second chapter, on "The volunteer

[1] *The Private Citizen in Public Social Work*. By Hilda Jennings, M.A.Oxon. With a foreword by the Hon. Lady Lawrence. An account of the Voluntary Children's Care Committee System in London: London: G. Allen and Unwin, Ltd. 1930. (6s. net.)

as fellow worker with the State," is indeed an admirable essay on its subject. The author goes on to trace the growing care of "the child as future citizen," and the development of the local machinery for effecting such care. The facts revealed with regard to such development in the social and educational sphere up to the war, during the war, and throughout the period of economy which succeeded thereto, demonstrate the really astonishing degree to which the London child of to-day is guarded and helped by a combination of voluntary effort and public organization. The intimate relationship between the children's care committees and the teachers, the school medical service, other social agencies, and the London County Council itself is described. In this connexion attention may well be called here and now to the memorandum which the Board of Education issued on the initiation of medical inspection as a duty of education authorities. The Board "insisted that the new service could not be divorced from existing medical and sanitary administration, but should be regarded as an integral and vital part of the wider question of the health and physical condition of the nation. The offices of medical officer of health and school medical officer should be combined." It is much to the credit of the London County Council that it seized the opportunity to establish so effective a partnership of legislative, administrative, and philanthropic agencies in the work of social education. Many examples are given in Miss Jennings's book of the methods by which this work is done and of individual successes that have been achieved. The difficulties of voluntary workers and agencies and their potential dangers are not ignored, but the book concludes with a statement which the facts and experiences it relates seem to justify. "A society approaches its highest potential power as an agent for the promotion of the best social life only in so far as its individual members—by reason of whose social nature it exists—are conscious of the social bond and will to make it effective. If this is acknowledged there appear to be two main reasons for desiring the continuance of voluntary social work. In the first place, such work brings the individual volunteer into more intimate touch with his fellow citizens than does purely political effort directed towards Governmental activity; secondly, a wholly bureaucratic public social service involves the presentation of public social benefits with authority and an element of compulsion, whereas the use of the volunteer as the agent of society makes it possible to avoid any suggestion of external force, and to appeal for the free co-operation of the persons whose social capacity it is desired to promote. In so far as these persons voluntarily respond they, too, are raised to the status of intelligent and willing partners with the State, and the dynamic force of the social impulses of the community is thereby increased. For both reasons society gains by the social effort of the private citizen, which has a unique value precisely because it is voluntary and is based solely on his personal recognition of his social nature and obligations."

MEDICAL CINEMATOGRAPHY

THE first catalogue of medical cinematographic films to be published in this country has just been issued by Messrs. Kodak Limited. Though small—it includes the titles of but sixty films—it is well classified, its subjects being grouped appropriately under the following headings: anatomy, case records, dentistry, neurology, obstetrics, orthopaedics, physiology, ray therapy, research, surgery, veterinary science, and, of course, miscellaneous. Up to the present the cinematograph has been but little used in medical education. The valuable part it may play in medical research is admirably illustrated in the series of films prepared by Dr. Canti and his co-workers showing the growth of the tissue cells and the effects on them of irradiation, its use as a vehicle for presenting the method and spirit of scientific research was shown in the beautiful film produced by Sir Thomas Lewis and Dr. H. H. Dale on the occasion of the tercentenary of the publication of Harvey's *De Motu Cordis*. But it is in the daily routine of instructing the medical student in physiology, surgery, obstetrics, and subjects similarly capable of visual exposition, that the cinema should have an increasing use in the future. No one who has had to strain forward to watch from an awkward angle the hurried fumblings of a demonstrator in physiology; who has felt pardonable impatience as, during the hour devoted to a demonstration, the minutes have been swallowed up by some trivial detail that has gone wrong, could fail to appreciate the educational value of a cinematographic demonstration, in which the rate of projection is carefully chosen in relation to the subject, the "close-up" comes at the right moment, the command of the modern photographer, and the experiment proceeds in an ordered way to its proper conclusion. Using the method of direct demonstration it is possible, even under the best conditions, to show only those experiments that can be completed within an hour or so. The student misses altogether the kind of experiment that takes hours to perform, or he may see it only at odd moments during its progress, depending for the rest on textbook descriptions or lectures from his teachers. With the cinema much of what is at present described verbally may be demonstrated visually. In their catalogue Messrs. Kodak include a useful introduction on the general principles of cinematography, and the methods of making, editing, and projecting medical films. The films named in the list are intended for circulation exclusively within the limits of the medical profession, and the hire of these films can be negotiated only by or on behalf of medical men and women. The catalogue and full particulars about the hiring of films will be supplied to members of the profession on application to the Medical Department, Kodak Ltd., Kingsway, W.C.2.

A MACKENZIE BIBLIOGRAPHY.

IT is now five years since the death of Sir James Mackenzie, whose original mind was mainly responsible for the modern cardiology, and it is therefore by no means too soon to be presented with a *Bibliography, with Synopsis of the Original Papers, of the Writings of Sir James Mackenzie*.[1] The work, originally and piously undertaken for the sake of the staff of the James Mackenzie Institute for Clinical Research at St. Andrews, is now available for all who wish to obtain a bird's-eye view of Mackenzie's work during the last forty-one years of his active life. The summaries of papers (except those in German, which Professor K. F. Wenckebach of Vienna has abstracted) have been successfully made by Mr. W. B. R. Monteith of St. Andrews, and have been conveniently arranged under the headings of medical education and research, cardiology, miscellaneous and symptomatology.

THE Ingleby Lecture will be delivered at the University of Birmingham on May 22nd by Sir John Bland-Sutton, Bt., LL.D., Past-President of the Royal College of Surgeons of England. The title of his lecture is "The Blood Trail."

A GENERAL meeting of Fellows of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Friday, May 9th. Dr. John Murdoch, of the Brugmann Hospital, Brussels, will give a lecture on radium. The chair will be taken by the president of the society, Lord Dawson of Penn, at 9 p.m.

[1] *Bibliography, with Synopsis of the Original Papers, of the Writings of Sir James Mackenzie, M.D., F.R.C.P., LL.D., F.R.S.* By W. B. R. Monteith. London: W. Heinemann (Medical Books), Ltd. Pp. viii + 152. 15s.

THE PRACTITIONER'S INCOME TAX.

THE Inland Revenue authorities will shortly be expecting to receive the annual declarations for assessment, and a few notes on questions which often arise may afford some practical guidance. To avoid misunderstanding it should be stated that the notes which follow do not apply to the emoluments of whole-time employment. Such incomes are assessable under Schedule E, and are subject to somewhat more stringent rules as to the expenses allowable than general profits falling in Schedule D.

BASIS OF THE DECLARATION.

The financial year for which assessments are made is the year to the next April 5th, but tax on the income of that year is payable according to the amount of the income of the previous year, taking that year as ending at the date to which it has been customary to prepare the accounts of the practice. The date usually taken is December 31st, but it is sometimes found convenient to adopt the date from which a practice—or a share therein—changed hands. When a complete change in proprietorship takes place the proprietor for the period from April 5th to the date of change is assessable on the amount of his profits for that period, and the revenue authorities have the option of revising his liability for the previous year to bring it to the basis of *that* year. The new proprietor is assessable as having started a new practice—that is, for the period to the next April 5th on his earnings for that period, and for the year following that date on the amount of his earnings for his first twelve months; but at his own option that assessment can be reduced to the amount for the actual year. Where the change of proprietorship is partial—for example, by the withdrawal or advent of a partner—no change in the basic year is made unless all the individuals concerned elect (within three months) to have the liability dealt with as if the change were complete.

COMPUTATION OF THE AMOUNT OF PROFIT.

Receipts.

Professional men tend to regard their "income" as the amount of cash which their work brings in: a tradesman's cash profits are often absorbed by an increase in his stock-in-trade or the amount of debts owing by customers, so that he is compelled to have a more exact conception of profit. The Income Tax Acts, being of general application, must, of course, treat the professional man and the tradesman on the same footing, and it is beyond argument that what is called the "cash receipt" basis is unsound in theory, and is admissible in practice only where the circumstances can be shown to be suitable—that is, where the gross income is reasonably steady. If, for instance, the gross bookings average about £2,100, of which £150 is lost by bad debts, then the cash receipts are not likely to vary very much, and in the long run will certainly average about £1,950, so that neither the practitioner nor the authorities will suffer by adopting the cash basis. Trouble, however, is apt to arise in such a case when the practice changes hands. The purchaser's cash receipts in his first two or three years will not reflect the full value of his earnings, and the authorities will require him to adopt the "bookings" basis. So far as the vendor is concerned the cash which reaches him after he has ceased to practise is not assessable in his hands, because it merely represents the final in-gathering in cash form of past taxed income; but we have not infrequently found practitioners paying tax on such receipts, apparently because they had come to regard "cash receipts" as *ipso facto* assessable.

Assuming that for some reason the cash basis is not applicable, and that the amount of the year's bookings is to provide the starting point, it is important to remember that the Acts provide for the deduction of an estimated amount for bad and doubtful debts—not an aggregate percentage estimate, but a sum calculated by reference to the respective debts. The best way of dealing with this allowance is to make out a list of unpaid accounts—whether in respect of the year in question or of previous years—which are considered partially bad or doubtful; the amount of the anticipated loss should then be noted against each item in a separate column and the total entered. The deduction to be made will then be: (*a*) the amount of debts finally written off and omitted from the list as definitely bad, (*b*) the total reserve estimated as above, less the corresponding total for the previous year. Any amounts recovered which had been previously written off or reserved for as bad must be brought into the statement as additional receipts.

Emoluments received from appointments are in strictness assessable separately under Schedule E, but the authorities are willing to include them in the Schedule D assessment on the general income, and that course is usually more convenient.

Expenses.

It is proposed to discuss these under three heads, according to whether they are incurred: (*a*) specifically for professional purposes; (*b*) generally—that is, partly for professional and partly for private purposes; and (*c*) motor car expenses.

Specific Expenses.—Little difficulty usually arises with these expenses, which include cost of drugs and bottles, dispenser's salary, stationery and stamps, and, where a separate surgery is maintained, rent, rates, and the cost of lighting, heating, and cleaning it. The expense of maintaining the instruments, reference books, furniture, etc., used professionally is admissible; where "improvement" is effected only that part of the expense which was necessary for "renewal" can be deducted. Subscriptions to professional societies are in a somewhat peculiar position. It has been held judicially that only that part of the subscription that has been expended by the society can be deducted. Obviously that principle could not be applied in practice, and an arrangement is commonly made under which the society pays tax yearly on the unexpended balance of the aggregate subscriptions, it being understood that in such cases the individual member can then deduct the whole of his subscription in its own return.

General Expenses.—The only sound guide is that the proportion to be charged to the professional account should be reasonable. In the last resort the Commissioners of Taxes—that is, the appellate body in the locality or in London—are the final judges, but on such a point there is obvious room for difference of opinion. The main expense of this kind is represented by rent and rates; and such other expenses as lighting, heating, repairs and redecorations, cost of domestic staff, etc., frequently follow the ratio adopted. As a rough guide, half and half is often a fair ratio, except where a special site element comes into play, when the professional element may amount to two-thirds, or even more. In the normal case a point that is sometimes overlooked is that the garage is often a substantial element in rent, and is entirely professional, and that the accommodation provided for an assistant, or the surgery and waiting-room maid, or the chauffeur is similar in character. Sometimes a useful check on an estimate can be obtained by looking at the reverse side—that is, by calculating what is the amount of the balance attributed to personal accommodation, etc.—and considering whether it is a reasonable charge for the benefits obtained. Where the premises are owned by the practitioner the amount on which income tax is paid under Schedule A is regarded as a rent payable, and, of course, expenditure on repairs is also chargeable to the extent to which it applies to the professional part of the premises.

Motor Car Expenses.—These expenses need special consideration. Running costs usually give rise to no difficulty, except perhaps as to the exclusion of some amount for private use, but trouble often arises over the expense of maintaining the car equipment. Nearly always it pays in the long run to claim the depreciation allowance in preference to waiting to claim the expense of renewal when it occurs. For one thing, the advantage might just as well be claimed now instead of in the future, and, for another, the renewal cost may never be claimable—for example, the practitioner may leave the practice and find that he has lost the chance of claiming the accrued wastage of capital since the last renewal took place. If depreciation has not been claimed the expense of renewal can be regarded as a professional expense, but any improvement element must be excluded. If, for instance, a second-hand car costing £120 is replaced by a new one at a net cost of £200, only £120 of that amount can be charged for income tax purposes. If depreciation has been claimed, "renewal" expenditure cannot be claimed for the same financial year, but that ban does not apply to a claim for "obsolescence." That allowance is computed in the same manner as a renewal claim, except that the total amount of depreciation allowance received for the displaced car must be deducted. If, for example, in the case quoted above, £44 depreciation had been allowed in respect of two years' use of the second-hand car, the net obsolescence claim will be £120−£44=£76. It will be seen that the combined

depreciation and obsolescence allowances afford the practitioner fairly complete protection against over-payment of tax so far as car expense is concerned, and consequently make the agreement of the rate of depreciation a less important matter. A rate of 20 per cent. appears to be not uncommon, but in many cases the authorities object to allow more than 15 per cent. *This would be a serious matter were it not for the fact that* the aggregate allowance is equated by the "obsolescence" claim when renewal takes place.

BRITISH EMPIRE CANCER CAMPAIGN.

SIR JOHN BLAND-SUTTON, Bt., *vice-chairman, presided at the* quarterly meeting of the Grand Council of the British Empire Cancer Campaign, held on April 14th, when the following grants were approved: £2,500 to St. Bartholomew's Hospital towards the maintenance of its cancer research work for the year 1930, which will include the continuance and development of investigations into the deep *x*-ray treatment of cancer in certain sites of the body and the further study of malignant growths by slow-motion picture photography, which is now known as the "Canti film"; £950 to St. Mark's Hospital towards the maintenance of its cancer research work; £200 (making a total grant of £300) to the Yorkshire Council of the Campaign towards a special statistical inquiry carried out by it into the incidence of cancer as divulged by post-mortem investigations made at some of the principal Yorkshire, Scottish, and London hospitals. *The Council also confirmed the grant arranged by the* Finance Committee since its last meeting of £3,900 to the Middlesex Hospital towards the maintenance of its cancer research work for the year 1929–30.

The Council decided to convene an informal meeting of the scientific committees of the Campaign and some of those actively engaged in certain cancer research work in this country, for the purpose of reviewing the activities at present proceeding, and *to consider what further lines of cancer research might be* inaugurated. This informal meeting will take place shortly after the midsummer recess.

The Council approved the publication of a popular book on cancer which had been drafted by the Investigation Committee, and delegated all arrangements in connexion with the issue of the book to the Management Committee, which is responsible for the publication of the *Cancer Review* of the Campaign. This popular book will deal with all aspects of the cancer problem, and has been prepared so that it can be appreciated by the lay public.

It was reported that the British Dental Association had nominated Mr. C. H. Hawkins of Birmingham to serve as its representative on the Council, and that, Dr. Powell White having retired through illness, the Christie Hospital, Manchester, had nominated *Professor John Shaw Dunn* of the University of Manchester to serve as its representative on the Council.

ROYAL MEDICAL BENEVOLENT FUND.

DURING the first quarter of this year £2,562 has been voted in grants to 121 *applicants. Subscriptions and donations are* very urgently needed, as the number of applications received during the first three months of this year is even larger than that of last year. Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

At the last meeting of the committee forty-two grants were voted, amounting to £966. The following were some of the cases helped:

M.R.C.S., aged 76. Applicant suffers from advanced chronic glaucoma. He has lost the sight of his right eye, and is becoming more helpless. Applicant and his wife have no private income; he is in receipt of old age pension, £26 a year. Four married children contribute £88 towards the maintenance of their parents. Fund voted £40.

M.R.C.S., aged 59. Applicant is bed-ridden, with progressive paralysis in the legs. He was compelled to give up his practice in 1925. His savings had been invested in house property, but the income derived therefrom has fallen to £130. *He has to pay for nursing and attendance* in addition to board and lodging. Fund voted £20.

Widow, aged 55, of L.R.C.P. and S. Since the death of her husband in 1919 she has maintained herself and educated three children by keeping a boarding-house. The children have now all obtained posts. During the last two years, although the widow has been extremely hard-working and is very thrifty, the boarding-house has not brought in a profit. Rates fell into arrears, and debts were outstanding. Fund voted £40 to pay the rates.

Widow, aged 38, of M.R.C.S. On the death of her husband, who had been ill for several years with Bright's disease, she was left with £250 a year and eight children to educate. One has obtained a scholarship, Freemasons are paying part school fees for another, friends and relations are helping towards other school fees. Fund voted £25, and has asked the Royal Medical Benevolent Fund Guild to co-operate.

Daughter, aged 61, of M.D. Has been a companion-housekeeper from the date of her father's death till December, 1929, when her employer died. She has no private income, and is now staying with friends. Fund voted £26.

Nova et Vetera.

"THE SMOAKE OF LONDON."

A REPRINT OF EVELYN'S TRACT.

Fumifugium,[1] the protest against "the Smoake of London," issued in 1661 by John Evelyn, has been republished by Dr. R. T. Gunther as an Old Ashmolean Reprint. This quaint but still applicable essay is approached by several prefaces, one by the editor of the 1772 edition, who observes that *nearly half the children born and bred* in "the aer of London" die under 2 years of age, and considers their fate not less cruel than that of infants exposed in China. Then follows Evelyn's own dedication to Charles II, patron of the Royal Society, in which we get a vivid glimpse of the "pre-sumptuous smoake" rising over Whitehall and endangering the health of that intelligent and cynical monarch, while his sister, the delicate Duchess of Orleans, complains that the air irritates her breast. For she has come over from France, where, Evelyn constantly maintains, they arrange the matter of the air better. The writer then addresses the reader, expressing his indignation that man, "whose very *Being* is *Aer*," should not be able to breathe it purely, and lamenting that a noble city like London should be marred by "the avarice of a few."

Turning to his business, he discourses a little on the "nature of Aer" in a manner "conceited" in the old sense. "The Lucid and noble Aer clarifies the Blood, *subtilizes and excites it*": *and the poisoning of air is no* less fatal than the poisoning of water and meat. One feels that the ardent Evelyn would treat manufacturers, who laugh at fines for the emission of "black smoke," much as other poisoners. He dwells with rapture on the amenities of the site of London, a city whose evils are all *accidental. All its beauty is befouled by "that hellish* and dismal cloud of Sea-Coal": and its citizens breathe *a black vapour created not by mere culinary fires, but by* the tunnels of fumes emitted from the works of brewers, dyers, lime-burners, salt, and "sope-boylers." The city, he thinks, is so made to resemble "the suburbs of hell" rather than the imperial seat of an incomparable monarch. The denunciation of coal smoke that follows is written in the pungent and highly charged English of his time; his readers of this time will still sympathize with it. The year when Newcastle was besieged, he says, was a year when the orchards and gardens in the Strand bloomed and fruited like country enclosures.

After diagnosing further the deadly effects of this "thin black soot," which clogs life into more existence, and urging the College of Physicians to help him, since many patients prefer the dangers of a country empire to those of London air, he discusses his remedy, which chiefly consists in the removal of all trades that are a smoke-producing nuisance to a reasonable distance from London, five or six miles below the river, to marshy grounds where, he reasons, their corrosive blasts might even do good to the moist atmosphere. Other disagreeable objects, like slaughterhouses, might fitly join them there. But Evelyn's scheme and his corollary notion of surrounding London with a belt of pleached gardens, all sweet briers, jessamine, lavender, rosemary, gillyflowers, and other sweet odours, deserves to be read in its entirety, for if it be sometimes merely amusing, it is often very suggestive. The little tract is inspired by a civic enthusiasm, and thanks are due to another son of Oxford for its reissue at a time when smoke and smoke abatement are very much in the air.

[1] *Fumifugium*. By John Evelyn, of Balliol College, Oxford, in 1661. Now reissued as an Old Ashmolean Reprint in the year of the reforming of the Old Ashmolean Museum, which, like "*Fumifugium*," was dedicated to King Charles II, Founder of the Royal Society, Oxford: Dr. R. T. Gunther, Folly Bridge, 1930. (2s. 6d.)

Ireland.

Dublin Meeting of the British Orthopaedic Association.

A VERY successful meeting of the British Orthopaedic Association was held in Dublin at the Royal College of Physicians, on April 11th and 12th, under the presidency of Mr. R. C. Elmslie. The opening session consisted of short papers followed by a discussion. Sir William H. de C. Wheeler, who dealt with the operation of diaphysectomy, showed a patient from whom the lower third of the femur had been removed twenty-one years ago, and before the publication of the various communications on the subject by Stiles. X-ray examination showed perfect re-formation of bone; there was 3/4 inch shortening, but no limitation of movements at the knee-joint. Frank diaphysectomy was recommended for certain cases of unreduced fractures of the elbow in children; the limb should be kept in extension during the early formation of new bone. The process of repair was illustrated by lantern slides, and a recent case was shown to indicate the results which might be obtained. The president, Sir Robert Jones, Mr. McMurray, and others, discussed the paper. Professor H. S. Meade described the methods of treating fractures which he had seen employed at Böhler's clinic in Vienna; he strongly advocated the various procedures, and showed lantern slides of the results obtained. An interesting discussion followed. Mr. Bristow and Mr. Platt, who had seen Böhler at work, said that they had been impressed by his team work and the manner in which he dealt with special fractures, but they had not adopted his methods to any considerable extent. Mr. Walter Stevenson read a paper on the effects of radium emanations in softening scar tissue and reducing pain; his authoritative views on this subject were received with much interest. Mr. H. F. MacAuley described a series of cases of unusual infections of the hip-joint, and many interesting lantern slides were shown. In the discussion which followed Mr. A. B. Mitchell congratulated the speaker on the interest his communication had aroused. In the afternoon the association met at the Orthopaedic Hospital, Merrion Street, when a programme was arranged by Mr. W. S. Haughton and Dr. Stevenson; the latter demonstrated an operation for the cure of knock-knee, and showed some cases under treatment. Mr. Haughton presented about forty cases of orthopaedic interest, many of which had been operated upon successfully for the correction of old-standing deformity in the feet. The Naughton-Dunn operation had been followed by excellent results. The list of cases included congenital club feet, knock-knee, and multiple enchondromata.

The dinner of the association was held at the Shelbourne Hotel; Mr. Elmslie presided, and about fifty members and their guests were present. There was an excellent musical programme arranged by Mr. Haughton, the singing of Irish melodies by a quartette being a pleasant feature. Sir William Wheeler, proposing the toast of "The British Orthopaedic Association," asked the members to accept a most hearty welcome to Dublin. He believed that in the distant future, owing to the victory of preventive medicine, life would be indefinitely prolonged, and the surgical profession, as known to-day, would cease to exist. Orthopaedic surgeons would always remain, however, to deal with congenital malformations and deformities the result of injury. Sir William referred to the esteem in which Sir Robert Jones was held in Ireland and to the debt of orthopaedic surgery to his genius. After Mr. Elmslie had replied for the association, Mr. Bristow proposed the toast of "The Guests" in a happily worded and witty speech. Dr. Winter, president of the Royal College of Physicians, and Mr. Andrew Fullerton, president of the Royal College of Surgeons of Ireland, replied. Sir Thomas Myles and Dr. Leeper entertained the company with some amusing reminiscences. Mr. Haughton proposed "The Emeritus President, Sir Robert Jones"; this toast and the toast of "The President," proposed by Mr. Bankhart, were received with marked cordiality.

The morning session, on April 12th, was held at Mercer's Hospital, when Sir William Wheeler performed operations for genu valgum and for malunion of fractured femur. A number of cases were shown illustrating the results of bone grafting in spinal cases. A successful case of double arthroplasty of the knee-joint was presented. The programme included the demonstration of a patient, aged 85, with bony union following intracapsular fracture of the hip, and a case of fracture dislocation of the pelvis with multiple fractures of the transverse processes and coccyx without any resultant disability. The members were entertained to lunch by Messrs. Arthur Guinness, and were shown over the brewery, the largest in the world. In the afternoon a visit was paid to the St. Mary's Open Air Hospital at Cappagh, which is erected on an ideal site and is one of the most modern of its kind. The members were received by Mr. H. F. MacAuley, and many interesting cases were demonstrated. The visitors were satisfied that the treatment in this institution left nothing to be desired. Some of the members remained over Sunday in order to inspect the Countess of Wicklow Memorial Hospital at Arklow; this institution is largely for the treatment of adults in the open air. Sir William Wheeler and the local practitioners received the guests at the hospital; Sir John Lynn Thomas was present, and the party was joined by Mr. Roberts, Minister of Pensions, and Sir Lyle Webb, who were visiting Dublin on a tour of inspection. Lunch was provided by the Earl of Wicklow at Shelton Abbey. The visit to Arklow terminated a meeting which, by general consent, was a happy and instructive gathering.

England and Wales.

Home Ambulance Service.

THE committee of the Home Ambulance Service of the Order of St. John and the British Red Cross Society has issued its report for 1929. Since the committee was set up eleven years ago it has established 343 ambulance stations throughout the country from Northumberland to Cornwall. These ambulances work day and night and convey on an average over 2,000 patients every week. Nine new stations were equipped during the year. At the end of the war there was some doubt if an ambulance service could be usefully employed in civil life. The report gives an interesting comparison. It states that the casualties carried by ambulances in France and Flanders during the five battles in which British troops were engaged in 1915 were 100,000, while in 1929, when no disaster or serious epidemic occurred, the Home Service ambulances alone transported over 113,000. Reference was made, when commenting on the previous report in these columns, to the organization of a road service and mobile x-ray department. These supplementary services show a sustained and vigorous policy. The urgent need for developing a road service is indicated by the fact that during 1928 over 170,000 persons were killed or injured in road accidents. Besides providing first-aid boxes and huts along the roadside, members of the Order and the Society, skilled in first-aid work, spend week-ends and holidays at places where accidents are likely to occur. With the rapid increase in road traffic throughout the country it is the aim of the committee to enrol units in every town and village, but it emphasizes that a steady recruitment of trained voluntary workers is necessary to maintain and consolidate the results that have already been achieved.

Post-Graduate Teaching in Birmingham.

A William Withering Memorial Lectureship has been established in the Faculty of Medicine of the University of Birmingham, and this year's lecturer, Professor W. E. Dixon, F.R.S., will deliver a course of seven lectures, illustrated by lantern slides, on specific therapy, on successive Wednesday afternoons at 4 o'clock during the coming summer term. The first lecture, on May 7th, will comprise a survey of the history of medicine in the nineteenth century, leading up to the present position of the views held in respect of drug action, alkaloidal production in the animal body, and the significance of vitamins. The second lecture will deal with the mechanism of drug action as exemplified by digitalis and strychnine; and in the third lecture the specific action of the body alkaloids,

including adrenaline, thyroxine, and parathyroid secretion, will be considered. In the fourth lecture Professor Dixon will describe the ovarian and pituitary functions, and in the fifth lecture the specific action of drugs on nerves and nerve cells. The last two lectures will be devoted to chemotherapy. Members of the medical profession are invited to attend this course. On May 15th, at 4 p.m., Dr. C. W. Buckley, physician to the Devonshire Hospital, Buxton, will deliver a lecture on mineral waters in therapeutics, their scope and practical application. A course of post-graduate demonstrations will be given at the General Hospital, Birmingham, on Tuesday afternoons, from 3.30 to 5 o'clock, and at the Queen's Hospital on Fridays, from 3.30 to 5 p.m., commencing on April 29th at the General Hospital, and on May 2nd at the Queen's Hospital. The course will include demonstrations on medical, surgical, and gynaecological cases; nervous diseases; ophthalmic cases; diseases of the ear, nose, and throat; radiology; venereal diseases; and children's diseases. One demonstration on a Tuesday will be given at the Children's Hospital, Ladywood Road, Birmingham. The fee for the course is two guineas, and detailed timetables may be obtained from the clerk to the Clinical Board, the University, Edmund Street, Birmingham.

East Lancashire Tuberculosis Colony.

In 1920 the British Red Cross Society and the Order of St. John in East Lancashire began to establish, on an estate of 120 acres at Barrowmore, a sanatorium, training colony, and village settlement, primarily for ex-service men suffering from tuberculosis, but ultimately for general use. In his annual report of this institution for the year 1928–29, Dr. E. L. Sandiland, the medical superintendent, describes the active progress that is being made, with special reference to the good results obtained by occupational therapy. New admissions during the year under review numbered 160. An after-care clinic is now to be established to supervise the health of the settlers and to serve as an out-patients' department for their dependants. As the result of a gift from the British Red Cross Society the whole of the workshops are being rebuilt, and another donation has been received for constructing a new plant for making fire-lighters, which will be particularly useful for the employment of unskilled labour. Various products of the institution were exhibited at the Chester and Frodsham agricultural shows, and efforts are being made to secure a wider field for the disposal of the articles manufactured, as well as of dairy, garden, and poultry farm products. A handsomely illustrated booklet describing the Barrowmore Hall Tuberculosis Colony is obtainable from the secretary of the executive committee, Mr. L. Royle, 3, St. James's Square, Manchester. Wards are being equipped for the sanatorium treatment of acute cases and for artificial pneumothorax cases. Chalets are under construction in the woodwork department for the use of patients.

The London County Council and its Medical Officers.

The London County Council has appointed Dr. H. M. Pereira, Dr. R. H. Swindells, and Dr. Frederick R. G. Heaf to fill the vacant posts of medical superintendent at the Eastern, New End, and Colindale Hospitals respectively. The commencing salary at Eastern and Colindale is £900 a year, and at New End, £950, in each case with an unfurnished house. The number of applications received for appointment to these positions was 103. The Council has decided to appoint a consulting radiologist at a remuneration of 200 guineas a year; the work is regarded as comparable with that of the Council's consulting ophthalmic surgeon, who receives a fee to that amount. Many matters relating to the x-ray installations in the transferred hospitals have come up to the Council for decision already, and such apparatus has been or will be installed in most of the Council's general and special hospitals. In view of the importance of the work, and the necessity of ensuring that apparatus is not only suitable and efficient for its purpose but is properly constructed and adequately protected, it is considered essential that there should be facilities for the medical officer to obtain the advice of an expert radiologist. Another matter which has been under consideration by the Central Public Health Committee is the conditions under which study leave and absence for study purposes should be granted to assistant medical officers. It is proposed that in those cases in which the officer continues on duty at the hospital or institution and only requires occasional daily leave for the purpose of attending a course of instruction for a medical degree or diploma, facilities should be granted for such leave on full pay; also that leave of absence for a period not exceeding six weeks in any one year be granted to an assistant medical officer desiring to undergo a course of medical instruction at a university, such leave to be on full pay in the case of officers of five years' service, on half-pay in the case of officers of two years' service, and without pay in the case of officers of less than two years' service. It is added that all such leave must be subject to the general condition that it can only be granted so long as the work of the hospital is not likely to suffer.

Infant Welfare and Maternity Centre.

An infant welfare centre for subscribers was started about six months ago by the Association of Infant Welfare and Maternity Centres. Members are enrolled only with the consent of their private doctors. This rule was made after hearing the views of the Maternity and Child Welfare Subcommittee of the British Medical Association. Preliminary work has been hampered by lack of funds for advertisement and equipment, but an increasing membership is reported. Medical and nursing services are voluntary at present, and rooms are occupied at a nominal rent. Whether there is need for a service of this kind is expected to be apparent in the next few months. The association now controls and finances three convalescent homes for infants and children; two of these are also used as nursery training schools. Experience has shown that the most satisfactory results are obtained in small homes where the number of children does not exceed a dozen. There is an urgent need for more of these during the summer months. A grant is received from the Ministry of Health for each home, and a certain amount is recovered in fees, but the annual deficit on this work is stated in the report for 1929 to be about £1,500. Income from the publicity department, however, increased from £1,617 to £1,790. Of the 384,000 publications that were sold, over 91,000 were books and pamphlets. The association is also concerned with the provision of holidays and convalescence for mothers, and of playgrounds for children between 2 and 5. More than one-third of the vacancies registered in the infant welfare workers' employment bureau were filled during the year. The report records that sixty-three affiliated centres were enrolled in 1929. Consideration of the amendment of the constitution of the association is expected to be resumed in the course of the current year.

Venereal Diseases: Lordon Arrangements for Diagnosis and Treatment.

The arrangements for the diagnosis and treatment of venereal diseases in London under the control of the London County Council have been continued for another year. The total number of new cases from all areas attending the London hospitals which received grants in aid under the Council's scheme during the year just ended was 15,985, with 768,872 attendances. The corresponding numbers last year were 16,401 new cases and 763,535 attendances. Of the total number of new cases last year 4,931 were syphilis, 10,774 gonorrhoea, and 280 soft chancre. The number of pathological examinations made at hospitals at the request of, and free of cost to, medical practitioners in 1929 was 32,605. The grant hitherto made to the British Social Hygiene Council in respect of local propaganda work in London is to be continued under the same conditions as in previous years, except that, at the request of the Education Committee, no educational work in the form of lectures to teachers will be included, the committee being of opinion that any such lectures to teachers which may be considered desirable by them should be undertaken by the Council's own medical staff. The estimate of total expenditure for the coming year on treatment and pathological work at hospitals and on hostels and preventive homes is £107,560: of this sum 17 per cent. is contributed by nine out-county authorities which make common use of the facilities afforded by the selected London hospitals.

Scotland.

Whole-time Medical Service in Fifeshire.

On April 16th a deputation from the Fife Branch of the British Medical Association met the Public Health Committee of the new county council of Fifeshire at Cupar in regard to the proposed reorganization of public health services in this county. The deputation included Dr. Fleming (Dunfermline), Drs. Douglas and MacTier (St. Andrews), Dr. Johnstone (Leven), and Dr. Dickson (Lochgelly). Dr. Douglas said that the public health services of administration and the clinical services rendered by the family doctor should be kept distinct as far as possible. The new Act placed upon the county council the responsibility for three very important lines of activity. The first concerned children and dependants; the medical profession was generally of opinion that these should be dealt with in future under the same conditions as insured persons. In Fifeshire the medical arrangements which had already evolved under the care of general practitioners had been very satisfactory, and it was hoped that nothing would be done to disturb them. The second point which had to be considered by the county council was hospital accommodation. The third responsibility had reference to the Poor Law. This was causing practitioners in Fifeshire some anxiety, for they believed that the treatment of the sick poor should be left in the hands of practitioners, and it would be a retrograde step to place this duty in the hands of district medical officers of health. The public health officer knew nothing about the domiciliary treatment of poor persons, and it would be unfortunate if men who had been solely concerned with the prevention and administrative control of disease were to displace those who had been doing clinical work all their lives. The whole country, irrespective of class, had fought for and won the principle of free choice of doctor, and this principle must continue. Dr. Dickson (Lochgelly) said that the good effect of unification of medical services would be lost if area medical officers were to be engaged in the treatment of cases for which they had no special training. If such officers were to give domiciliary treatment to the sick poor this would lead to class distinction between Poor Law patients and other patients, which would be invidious. The practitioners in Fife were prepared to undertake all the necessary clinical work for which the county council was responsible under the new Act. The county council afterwards appointed Dr. Pratt Yule medical officer for the county, Drs. Fyfe and M'Gillivray assistant county medical officers, Dr. Leask tuberculosis officer, and Dr. Krause medical officer to supervise school children and child welfare. It was resolved to consider the statements made by the deputation before any further steps were taken.

Glasgow Slum Clearance.

A scheme for slum clearance in Glasgow, promoted by the corporation and involving the demolition of a large number of dwellings in the Calton district of Glasgow, was considered by a commission on April 15th. It was explained that this was the fifth of a series of schemes, which affected about 50,000 persons and 14,000 houses. The general death rate for the area was approximately 22.5 per 1,000, as compared with 13.8 for the city generally, while the death rate from pulmonary tuberculosis was 1.69, as compared with 0.84 for the city; the infant mortality was 141 per 1,000 births, as compared with 106 for the city generally. Dr. A. S. M. Macgregor, medical officer of health for Glasgow, gave evidence showing the urgent need for dealing with the problem of insanitary houses and areas. The clearance proposed at present affected 1,311 houses with a population of 5,151. These houses consisted of 611 houses with one apartment, 636 with two, and 61 with three apartments; 55 of the houses were occupied by more than one family; the houses regarded as definitely insanitary numbered 1,184; the remaining 127 houses, although fit for habitation, were included to make the scheme efficient. The density of population in these houses was revealed by the fact that the number of houses per acre was 105, and the population 418 persons per acre. This overbuilding had the effect of narrowing available courtyard facilities and preventing free access of light and air. Many of the houses were over one hundred years old and showed defects of age, being dilapidated in several cases and having no damp-proof courses. The total cost of the scheme is over £590,000, and, spread over a period of sixty years, is estimated to cost the municipality an increase in rating of one farthing in the pound.

Edinburgh Skin Dispensary.

The annual report of the Edinburgh Dispensary for Skin Diseases showed that 556 patients had been treated during the past year. Lord Murray, in moving the adoption of the report at the annual meeting, said that pleas were sometimes made that there was overlapping and waste among the charitable institutions of Edinburgh, but he believed that there was more than room for all of them, and he commended the work of this institution to the generous support of the citizens of Edinburgh. Dr. Robert M'Laren, medical officer to the dispensary, said that the dispensary not only made out prescriptions, but paid for their cost, and in this way the dispensary met the needs of those who could not afford to pay anything for their treatment.

Presentation to Dr. David Black.

On the occasion of his retiring from practice, Dr. David Black of East Linton was entertained recently to dinner, at Haddington, by his colleagues of East Lothian, and presented with an inscribed silver cigar box. Dr. Martine, who presided, gave an account of the changes in the medical profession of East Lothian during the past thirty-five years, and recalled how Dr. David Black, who had started practice in East Linton more than forty years ago, had built up a large country practice and had become widely popular; he had taken great interest in public work in the community, being for some time a member of the East Linton town council and latterly a magistrate. He had served for many years as a trooper in the East Lothian and Berwickshire Yeomanry Cavalry, regularly attending their annual training camp. He was a keen member of the British Medical Association, and had been president of the Lothians Division. Dr. Martine added that Dr. Black would be greatly missed, but he hoped that he would be long spared to enjoy his well-earned leisure.

India.

Eclampsia in Calcutta.

DR. GRACE STAPLETON, who is medical superintendent of the Dufferin Hospital, Calcutta, contributed to the March issue of the *Indian Medical Gazette* some statistical notes on the incidence of eclampsia in Calcutta. She quotes the paper on Indian medical statistics read by Dr. Margaret Balfour at the Congress of the Far Eastern Association of Tropical Medicine in 1927, and mentions that the eclampsia rate per thousand births in Calcutta is 41, as compared with 13.3 in Madras, and 9.7 in Bombay. There also appears to be a high case mortality in Calcutta, the percentage being 31.2 there; as compared with a figure of about 12 in the other two cities. Dr. Stapleton calls attention to the fact that in a very large majority of the cases eclampsia affected first pregnancies, and was mainly a disease of young women, aged 20 or under, the death rate among these being double that among older patients. The prognosis appears to be far more serious when fits occur in the later months of pregnancy. She concludes that a strong argument is thus forthcoming in favour of raising the marriage age and the time of consummation of marriage until physical growth has been completed. In the twelve months ending November, 1928, out of thirty-four girls, aged 16 and under, who were admitted to the Dufferin Hospital for their first confinement, no fewer than 11 (32 per cent.) had eclampsia, while others showed lesser signs of toxaemia. Emphasis is laid also on the importance of ante-natal care and systematic house-to-house visiting, so that early cases may be detected, and patients be persuaded to attend the ante-natal clinics.

Veterinary Research in India.

Part of the research work undertaken during 1928–29 by Dr. J. P. Edwards, director of the Imperial Institute of Veterinary Research, Muktesar, was an investigation into bovine piroplasmosis in Holstein stud bulls. The report of the Institute gives a brief summary of the symptoms of the disease, from which it appears that the only treatment available at present is careful nursing. Recovery is not considered to imply immunity from further attack, as serious relapses were recorded. The histological observations were not completed in time for this report, but they seemed to the investigators to consist of lymphocyte "blocks" in the smaller arteries of the principal organs. Although the bulls were inoculated against *Babesia bigeminum* and *Theileria mutans* before they were exported from South Africa, many of them were affected at the same time, shortly after their arrival in India. This appeared to indicate that the pathogenicity of the theileria parasite of India differs from that of the South African species. On the other hand, some evidence was obtained of the identity of *B. bigeminum* in the two countries. Preliminary research was also conducted on foot-and-mouth disease on the lines of Waldmann and Pape. Experiments with guinea-pigs revealed that the virus caused regular vesicle formation on the plantar pads in twenty-four to thirty hours. In addition to research on numerous diseases the Institute manufactures over a dozen different serums and vaccines; the total issue for the year was 63 million doses. No serious epidemic occurred at Muktesar, but the improvement of sanitation and drainage was the subject of a Government report.

Prevention of Malaria in the Punjab.

During the months of July, August, and September, 1928, an investigation was made by Drs. M. Yacob and K. S. Shah, of the Punjab Epidemiological Bureau, Lahore, with a view to determining the practical and financial feasibility of employing Paris green for the destruction of anopheline larvae on a large scale in the Punjab. Their report is published in the February issue of the *Indian Medical Gazette* (p. 84), and in it they state that it was found that an area treated with this larvicide remained free from anopheline larvae until the third day after its application, when very young larvae reappeared. A dilution of 1 gram of Paris green in 89 grams of road dust was sufficient to destroy all anopheline larvae in ten square yards of water surface in twenty-four hours; culicine larvae, leeches, and tadpoles were not affected. A similar experiment was made with 0.5 per cent. of Paris green, but this was found to be capable of destroying rather less than 50 per cent. of the larvae in the twenty-four hours. Laboratory experiments indicated that this larvicide does not affect the egg and pupal stages of anopheline mosquitos, nor does it prevent the adult mosquito from laying eggs. Intervals between the application of Paris green should not exceed six days. From the financial point of view the widespread use of this measure seemed to be justifiable.

Progress of Vaccination in Burma.

In seventy-three towns in Burma, during 1928–29, over ten thousand infants died from various causes before their first birthday. This information is revealed, incidentally, in a triennial report on vaccination in the province for 1926-27 to 1928-29. Parents in Lower Burma, especially those living in remote areas, are reported to be reluctant to have their children vaccinated before the end of the first year. Serious opposition to vaccination, however, occurs only in a few backward and primitive areas, but people willingly submit during outbreaks of small-pox. Evidence is accumulating of a more widespread recognition that vaccination is a means of protection, for, while the incidence of small-pox was less than in the previous triennium, the number of vaccinated cases exceeded that of the two previous periods. More than 2½ million vaccinations were performed altogether, an increase of over 100,000, about 1½ million being primary. Following the extension of compulsory Acts to rural areas the figures for both primary and revaccinations showed a steady rise up to 1928–29, which marked a record. In this year the rate of success in primary cases was 97.11. Since the last report Vaccination Acts have been extended to Shwebo and Mandalay. On the other hand, there were fewer primary vaccinations in seventeen districts, and fewer revaccinations in eighteen. These decreases are accounted for by economy in lymph supply, difficulties of communication and transport, and disinclination of the people during non-epidemic periods. It took ten days to convey lymph to the Chin Hills, where the lowest rate of success was reported: its potency was thus reduced in transit. In several districts the people were willing to have their children vaccinated, but they objected to taking them for verification to the health or inspecting officers. Lieut.-Colonel G. Jolly, I.M.S., director of the public health department in Burma, anticipates that further progress will be made throughout the province by more intensive propaganda, but he urges the need for developing a rural health service to ensure more efficient supervision.

Correspondence.

ANTIMALARIA MEASURES.

SIR,—With reference to the letter of Colonel C. A. Gill, I.M.S., in the *Journal* of April 12th (p. 718), may I point out that mosquito control is only one item of vermin control or pest control, both of which are extensively used in many countries? Such control must always cost money, but is adopted because local authorities, such as agriculturists or other inhabitants, think that the benefits are likely to exceed the expenditure. If, of course, malaria could be controlled by cheaper methods, one would be only too glad, but I doubt whether it can be done.

Owing to the scarcity of malaria and of mosquitos in England few people here take much interest in these subjects, and can easily be imposed upon by mistaken opinion. There is only one school of competent malariologists—those who do the work. But the work of mosquito control is monotonous and not very profitable to the worker, though certainly very valuable in a malaria-infested area. Many people seem to think that malaria control is responsible only for expenditure; they forget that the disease itself costs much more money.—I am, etc.,

London, S.W.15, April 17th. RONALD ROSS.

INDIAN MEDICAL DEGREES.

SIR,—In his letter (April 12th, p. 717) on the above subject Lieut.-Colonel R. H. Elliot writes that he believes it will be accepted on all sides that the General Medical Council of Great Britain is in no way actuated by hostility towards India in withholding further recognition of Indian medical degrees. Any unprejudiced and careful student of the facts in this unfortunate controversy must agree that the Council was reluctantly compelled to take the action it has done. Recent utterances by prominent Indian members of the medical profession in Bombay and elsewhere in India make it clear, however, that in their view the Council has been interfering and dictatorial, if not actually hostile.

Recently, while I was surgeon-general with the Government of Bombay, I travailed (I regret to observe, ineffectually) to convince various leaders of the independent medical profession in Bombay that the attitude of the Council was benevolent. It had no desire, I explained, to interfere in matters of medical education in India, but it could not but insist that all those registrable in Britain should be adequately trained according to British standards. If the Council could not get evidence of satisfactory training from a source on which it could implicitly rely the withholding of recognition was quite inevitable. It seemed to me, however, that in many cases I made my appeal to minds that had for various reasons insulated themselves against any current of sympathy with the difficulties of our Council in the matter.

I hope, with all well-wishers of India, that it may again shortly become possible to accord recognition to Indian medical degrees. The Council cannot, however, be expected to recede, on political grounds, from the position it has been forced to take up.—I am, etc.,

St. Raphaël-Valescure, Var, April 15th. R. W. ANTHONY, Major-General I.M.S. (ret.)

STERILITY IN WOMAN.

SIR,—*Professor Blair Bell's address on female sterility* (April 5th, p. 629) lends itself to discussion. I agree with him that curettage for primary sterility is not necessary, but I doubt whether, when reasonably performed, there is more than a negligible risk of producing tubal inflammation.

He does well to hesitate when he declares that it appears probable that about 40 per cent. of all cases of sterility in women are due to infection—apparently largely tubal infection—for he judges that cervical infection as a cause of sterility is "perhaps infrequent." I am not in a position to give any reasonable opinion as regards the cervix, but I am glad to support him in his view that the endometrium has a capacity for escaping, perhaps better expressed as overcoming, even serious infection that should put to shame those who talk and write of "chronic endometritis" as a common lesion. In my own opinion the great bulk of primary sterility is produced mechanically by tilting forwards of the cervix. Professor Blair Bell apparently includes this under the heading of "conical and hypertrophied cervices"; I prefer to name it anteflexion of the cervix; the os in such cases points precisely as it does in a case of retroversion, and indeed it is sometimes difficult, in a fat or rigid woman, to differentiate. Why, by the by, does he recommend operation for retroversion, when a Hodge pessary so easily and efficiently maintains the correct position? After the first labour, the position of the os seems to matter less, perhaps because it is more patulous.

I differ from him most when he asserts that patency tests have proved, in his experience, that 35 per cent. of cases of sterility, without physical signs or symptoms, have occluded tubes. My own positive results, under the above conditions, reach something like 95 per cent.; in fact, it is a rarity to find occlusion, or a result that suggests it, where one has no reason to expect it from bimanual examination. I must emphasize that the apparatus I use (Victor Bonney's) is tested before each procedure, and that leakage is controlled by a head of saline in the vagina. Professor Blair Bell has never found this latter necessary, but I believe I may find it very useful if he attempts to query my large percentage of positive results. It would be interesting and important to hear the views of other workers on this point. I rarely go above a pressure of 210 mm. of mercury; in a very large proportion of nulliparous women air readily passes between 140 and 160 mm. and in parous women at about 80 to 100 mm. I fail to understand Professor Blair Bell's generalization of 80 mm. for the type he is discussing. In exceptional cases, when repeated trials (at one sitting) have proved negative, I have gone as far as 230 mm. or even 240 mm. In a few of these cases I have had an immediate opportunity of inspecting the tubes; in no instance has there been any evidence of rupture. I can hardly believe that spasm of the tubes would resist a pressure approaching 200 mm. of mercury. I am of opinion, therefore, that Professor Blair Bell's high percentage of negative results is an artefact pure and simple, and that a better technique would have produced results more approximate to my own. I will not delay the argument by detailing the refinements that are necessary. In cases of relative sterility, without physical signs or history, I agree with him that in some cases "ventilation of the tubes" (as I like to call it) can produce very happy results.

Professor Blair Bell, appreciating that 14 per cent. to 20 per cent. of sterile marriages are due to the husband, insists that no woman is to be subjected to unpleasant examination or treatment for sterility *per se* until her husband has been proved. But surely he does not find it possible to test the husbands of women of hospital class. For years past, in private practice, I have endeavoured to have all husbands tested, and a small percentage has been found unsatisfactory. Within the last two years, in two such cases, to my consternation, there have been threats of suicide on the part of the husband. Since this painful experience I have continued to request, but have refrained from insisting on, examination of the husband. We can say, in the absence of marked physical signs, that a woman is absolutely incapable. On the other hand, negative tests in a man, possibly temporary, are more explicit, and may involve domestic disaster. In general, it seems unfair to deprive a sterile woman of treatment because her husband cannot (as in hospital practice) or will not (as occasionally happens in other circumstances) be investigated, when we know that in about 50 per cent. of the cases the woman is at fault and usually presents evidences of that state.—I am, etc.,

Liverpool, April 15th. H. LEITH MURRAY.

THROAT INFECTIONS AND PUERPERAL SEPSIS.

SIR,—An almost identical experience to that of Dr. A. S. Garden at Southport Maternity Hospital (April 5th, p. 666) has occurred in the Burgh Maternity Home, Kilmarnock. The particulars are as follows.

Mrs. S. was confined on March 10th. The labour was normal, but rather slow, and as her general condition was poor low forceps were applied by the private practitioner. Seven days later (March 17th) she had a rigor, the temperature rising to 102° F.

Mrs. M. was confined on March 18th. Instrumental delivery was effected by a different private practitioner. Three days afterwards (March 21st) she developed a temperature of 102° F.

Mrs. Sh. was confined on March 21st. She was attended by a third private practitioner and had a normal delivery. Seven days afterwards (March 28th) she developed a temperature of 101.8° F.

As we were at a loss to know the cause of the occurrence in an institution which for many years has been singularly free from puerperal troubles, a consultation was held with two of the local practitioners keenly interested in the matter (Drs. Frew and Peden). As a result, the staff, nursing and domestic, were submitted to medical examination without any obvious focus of sepsis being discovered. It was then suggested that the throats of the entire personnel of the home be swabbed. This was done, and in the case of one nurse haemolytic streptococci were found. She was at once taken off duty and, to date, no further abnormal temperature has been noted. It is interesting to note that the nurse in question was not present at any of the three actual confinements, but assisted in attending to the toilet of the patients afterwards.

It has now been arranged that gloves and masks are to be worn by the staff, whether assisting at confinements or performing the swabbings of the patients subsequently.—I am, etc.,

Kilmarnock, April 18th. B. R. NISBET.

CORONARY OCCLUSION.

SIR,—In the issue of the *British Medical Journal* for April 12th there are two papers on disease of the coronary arteries—one by Dr. Crighton Bramwell and the other by Drs. Herapath and Perry. In addition, there is a leading article upon the same subject. Dr. Bramwell states that syphilis does not play a significant part in the etiology of the condition, and with this opinion the leading article agrees. It is stated that Levine found syphilis to be present in only 4.5 per cent. of cases, and that he doubts whether the disease "has any direct causative influence on the production of coronary thrombosis."

One would point out that in the cases described, the criteria for the absence of syphilis are quite inadequate. The syphilologist is very well aware of the fact that a high proportion of patients suffering from syphilitic disease of the heart return a negative Wassermann reaction, and in the vast majority one may be unable to elucidate any history of that disease. Unless the hearts of patients dying from coronary disease—or with symptoms suggesting it—are examined microscopically after the method of Warthin, any opinion as to the absence of syphilis is valueless. Syphilis is essentially a disease of the cardio-vascular system, and histological post-mortem findings show that many of the symptoms which have been attributed to disease of the coronary arteries are really due to myocardial damage. The terminal branches of the coronary vessels are end arteries, and it is around these terminal arterioles that in syphilis there are found large areas infiltrated with lymphocytes and plasma cells. This progresses towards fibrosis and may result in blocking of the vessel. Severe coronary sclerosis is rare in syphilis; and where involvement of these vessels does occur, the cellular infiltration is perivascular rather than vascular. At the necropsy table, cases which exhibited anginal symptoms may show very slight, if any, coronary

sclerosis, although the fibrosis present in the myocardium may be very striking. It would seem, then, that the clinical signs described by Dr. Bramwell, and interpreted as coronary occlusion, are consistent with myocardial damage alone.

The commonest visceral lesion of syphilis is a myocarditis, which is more often than not invisible to the naked eye, and can only be demonstrated by the microscope as an infiltration by lymphocytes and plasma cells along the vessels between the muscle fibres. The favourite site for syphilitic myocarditis is just above the apex of the heart on the anterior wall of the left ventricle. The epicardium and endocardium in this area become thickened and roughened, and give rise to that transient pericardial friction referred to by Dr. Bramwell. It is in this area that aneurysm and rupture of the heart are apt to occur. The position would appear to be that although syphilis may not be a frequent causal factor in coronary thrombosis, it is a common cause of a myocarditis which gives rise to all clinical signs consequent upon occlusion of a coronary artery. In other words, a syphilitic myocarditis can cause a lesion exactly equivalent to the end-result of a coronary occlusion.

Experience would seem to show that myocarditis is the invariable accompaniment of syphilis, and that commonly there occurs along with it a perivascular fibrosis of the terminal branches of a coronary artery (usually the left). This establishes a vicious circle; and the site of the greatest fibrosis and myocardial degeneration is on the anterior wall of the left ventricle just above the apex. In a coronary vessel narrowed by obliterative endarteritis due to syphilis, thrombosis is apt to occur, resulting in sudden death or in the clinical condition described by Dr. Bramwell. I suggest, therefore, that the clinical condition to which Dr. Bramwell refers, and which is usually dubbed "coronary" occlusion," is very frequently a localized myocarditis pure and simple; that it is frequently due to syphilis; that the coronary arteries may become a seat of a later obliterative endarteritis; and that thrombosis may occur in such vessels, and when it occurs suddenly death is, as a rule, equally sudden. Dr. Bramwell rightly lays special emphasis on the frequency with which the heart condition gives rise to acute abdominal symptoms, a wrong interpretation of which may result in a useless and perhaps fatal laparotomy. The number of syphilities bearing laparotomy scars is very high; and it is significant that the operation has usually been performed two or three years after syphilis has been acquired.

Much useful information might be obtained if cases of alleged coronary occlusion coming to the post-mortem table were investigated by the histological method of Warthin, which was shown to be of such high value at the Annual Meeting in Manchester last year. The presence of a negative unprovoked Wassermann reaction and absence of a history in no way rule out the syphilitic etiology. There is no branch of medicine in which the therapeutic test for syphilis, by means of bismuth and the careful exhibition of iodides or by intramuscular sulfarsenol, has a greater value than in cases of myocarditis.—I am, etc.,

E. TYTLER BURKE,
Director of Venereal Diseases Treatment Centre, City of Salford.

April 15th.

SPINOCAIN ANAESTHESIA.

SIR,—I am interested in Dr Hudson's case of death during spinocain anaesthesia (April 12th, p. 693). I have used spinocain on many occasions, and have seen no difficulties occur when it has been administered strictly according to Pitkin's directions.

But I would not care to inject at the level of the eighth dorsal vertebra, for it seems to me that by so doing the margin of safety would be materially reduced. For high anaesthesia, if one injects between the third and fourth lumbar vertebrae, and reinjects three times, allowing four minutes before inverting the patient, it is possible to watch the spread of the anaesthesia, and to invert at a period of less than four minutes if necessary, and so limit its further action. Pitkin suggests that one can inject as high as the first lumbar vertebra "for quicker anaesthesia," but speed cannot be regarded as necessary.

Spinocain is a marked improvement on the old stovaine, the use of which was often followed by collapse of the patient. I feel perfectly happy in using spinocain on all occasions where a general anaesthetic is contraindicated—for example, operations for gall-stones, prostatectomy, and all rectal operations of long duration.

It would be a pity if one death following an injection at the level of the eighth dorsal vertebra should influence anyone against a method that affords such distinct advantages.—I am, etc.,

C. L. GRANVILLE CHAPMAN, F.R.C.S.I.

Grimsby, April 19th.

DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS.

SIR,—In his letter (April 5th, p. 653), Dr. J. R. Gillespie, who has for many years been known as a consistent advocate of tuberculin, both in diagnosis and in treatment, ranges himself alongside Dr. Weatherhead (March 19th, p. 516) in upholding the importance of subcutaneous tuberculin as a diagnostic agent. He minimizes Dr. Weatherhead's opinion of the risks involved. The latter wrote "even this" (a mouth temperature of 99.2° F.) "is running the risk of a dangerous focal reaction." How mild is Dr. Gillespie's paraphrase—"Dr. Weatherhead's statement, as I understand it, was only to the effect that giving test doses to patients whose mouth temperature runs as high as 99.2° F. involves some risk."

These two protagonists have more essential variances. Dr. Weatherhead says of the subcutaneous tuberculin test that it is "of small value on the positive side. . . . No doubt a large proportion of cases will give a positive reaction, leaving the diagnosis still in question." Dr. Gillespie, on the other hand, reports 764 cases in which the diagnosis could not be established by ordinary means, presumably including x-ray examination, and in which he used subcutaneous tuberculin as the "deciding factor." He found 454 positives, and did not hesitate, on this ground alone, to advise a course of treatment extending over at least six months. "The great bulk of those who took this advice got quite well." Dr. Weatherhead, presumably, will not be greatly surprised at such a wholesale cure of pulmonary tuberculosis diagnosed by this procedure. But they agree on the extreme importance of a negative finding. Dr. Gillespie, with admirable fairness, sets out his obvious known failures.

It can only be said that a patient who has received, to his great comfort and that of his friends, a definite assurance that he is not suffering from tubercle, and who nevertheless is within six months a frank case of open pulmonary tuberculosis, is little likely to be impressed, or comforted, by Dr. Gillespie's comparison of the efficiency of his eliminating test with that of the Wassermann reaction. And in case the opinion of the patient is regarded as of no consequence on such a matter, I should like to quote the opinion of Dr. S. Roodhouse Gloyne, who certainly speaks with commanding authority on these subjects. In a paper published in *The British Journal of Venereal Diseases*, October, 1923, he discusses the differential diagnosis and interaction of syphilis and tuberculosis in lung disease, and states: "I have refrained from discussing the tuberculin tests because I do not regard them as good tests of the activity of tuberculous disease."

Dr. F. A. Hort (April 5th, p. 663) raises two points, the first of which concerns the use of tuberculin in treatment; he asks why it is not used to any extent. In my case the answer is simply that I have not found it of any appreciable value. The other point is a request for practical detail in exploiting the psychical factor. Possibly an expert psychologist could furnish this, though it is doubtful. A doctor prescribing any treatment in which he firmly believes is consciously or otherwise exploiting the psychological factor. Every successful doctor thrives on it, wittingly or not, though methods vary widely. The use of tuberculin, in suitable hands, and particularly if the diagnosis is not too rigid, is capable of great influence in this respect.

May I add a word on Dr. Esther Carling's letter (March 22nd, p. 567) dealing with the policy of submitting debilitated patients with advanced though chronic disease

to the rigorous winter conditions of many sanatoriums? I am sure it is, as she says, futile and sometimes even cruel. Reform is highly desirable, and I trust her practical suggestions will receive the consideration they merit.—I am, etc.,

Gloucester, April 14th. W. ARNOTT DICKSON.

SIR,—The tuberculin test is certainly not infallible, but anyone who has used it extensively can hardly fail to recognize in it a most valuable adjunct to other methods of diagnosis. The test being one of immunity there is no reason why a tuberculinized individual who has developed a partial active immunity to the toxin of the tubercle bacillus should give a marked positive reaction. But he will surely react in a modified way in proportion to the amount of immunity he has developed. In a case of chronic fibroid tuberculosis where the plasma is flooded with autogeneous tuberculin, and when this toxin produces little or no toxic effect on the host, we need not expect a small quantity of injected tuberculin to have any appreciable reactive effect; the reactive phenomena are therefore minimal, but they are always present, especially if the subcutaneous test is employed. In the very acute type of tuberculous infection, particularly in young girls, where the reactive processes of the individual have been broken down completely, we cannot expect tuberculin to produce a reaction. In both of these types—the extensive chronic fibroid and the acute disseminated type of infection—we do not need the tuberculin reaction for a diagnosis. In the first type of infection physical signs and symptoms are obvious, and in the second type there is nearly always a typical *x*-ray picture.

Many years ago I used the Pirquet method; but I certainly found the result difficult of interpretation, because in this test the only guidance is a local manifestation. The tuberculin reaction is a complex, there being not only the specific element but also a purely toxic element in it, the second being probably of a protein shock nature. On the other hand, with the subcutaneous test, the picture is complete, with a local reaction, a characteristic temperature response, and the focal reaction; the last, when obtained, is certainly diagnostic of an active and progressive tuberculous lesion. I have employed the old tuberculin of Koch in diagnosis (by the subcutaneous method) in several hundred cases, and I have never yet seen mobilization of the tubercle bacilli as a result of it, although anybody who reads the alarmist literature on the subject would undoubtedly be frightened at its use.

During the war I had a curious experience. A fresh supply of the old tuberculin of Koch had been supplied to me by an English firm of manufacturers; I could not get a definite and typical reaction in cases which obviously ought to have responded thus. I became suspicious, and after a good deal of trouble I obtained from a foreign firm another supply of tuberculin, prepared in accordance with Koch's original formula, when I had no difficulty in obtaining a typical local, general, and focal reaction in those cases which had previously failed to react. A few years later I received from a well-known London physician a supply of tuberculin; he stated that he had been unable to obtain the reaction with it, but unfortunately at the time I was unable to test its properties in obviously tuberculous patients. I have no doubt that occasionally a tuberculin is encountered which, through faulty preparation, is of no value as a diagnostic agent.

Another method of real diagnostic value, which ought to be used more extensively, especially by the general practitioner who sees the case early, is the method of auto-intoxication excited by gradually increasing walking exercise. An apparently afebrile patient, in the earliest stage of tuberculosis, will often develop a sustained temperature, lasting a week or more; if the patient is carefully examined every day the transient appearance of some definite sign (a focal reaction) will clinch the diagnosis. Obviously, complete rest in bed is indicated as soon as the diagnosis is established, until the temperature and pulse have gained their normal level. I have occasionally made use of this procedure when the subcutaneous tuberculin test was contra-indicated.—I am, etc.,

[illegible], April 7th. FELIX SAVY.

ERGOT PREPARATIONS FOR ORAL ADMINISTRATION.

SIR,—I should be greatly obliged if you would publish a correction of a statement in your article of April 12th (*p. 767*) *on preparations of ergot for oral administration.*

When referring to the examination by Elphick and myself of various samples of ergot, you stated that we found Polish ergot to contain 0.6 per cent. of the specific alkaloid. This figure should be 0.06 per cent. The error, which is due to my faulty proof-reading, requires correction because of the bearing of the facts on the future of these ergot preparations. The finding that Polish and Russian ergots, which constitute such a large proportion of the total production of this drug, contain so much less ergotoxine than the ergots from Spain or Portugal, may prove of importance in deciding the minimum amount of activity which will be permitted in extracts of ergot in the next edition of the *British Pharmacopoeia*.—I am, etc.,

London, W.C.1, April 15th. FRANK WOKES.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examination indicated:

DIPLOMAS IN PUBLIC HEALTH, HYGIENE, AND TROPICAL MEDICINE AND HYGIENE, PART I.—R. J. Dyson, M. S. El-Kinani, C. O. Karunakaran, J. H. *Loots* (distinguished). Flora H. G. *Macdonald*, Ethel Morris, K. C. K. E. Raja, Joan Robinson.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AT an ordinary meeting of the Royal College of Physicians of London held on April 14th, Sir John Rose Bradford was re-elected President of the College.

Diplomas.

The following Diplomas were also conferred, jointly with the Royal College of Surgeons, on the following candidates:

IN TROPICAL MEDICINE AND HYGIENE.—G. H. Arndt, S. Attaullah, Balkrishna, C. L. Bhola, R. C. Burgess, A. D. Cust, W. C. Davidson, Eugene Egan, A. P. Farmer, P. V. Gharpure, F. W. Gilbert, C. J. Hackett, W. R. Little, A. F. Mackay, N. M. Maclennan, W. A. Mirza, Z. Miterstein, S. K. Mitra, *C. C. Okell, G. M. C. Powell, J. T. Sorley, J. H. Strahan, W. K. Stratman-Thomas, S. H. Swift, G. E. Tilsley, E. A. Trim, L. E. Vine, *N. T. Whitehead, K. L. Wig, F. Williams.

IN C[illegible]

F. C. Wilson.

The Services.

I.M.S. DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London, on Wednesday, June 18th, at 7.15 p.m. Major-General F. G. H. Hutchinson, C.I.E., has been invited to take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Sir Thomas Carey Evans, *M.C.* (Major, ret.), 31, Wimpole Street, W.1.

DEATHS IN THE SERVICES.

Lieut.-Colonel William Snowdon Hedley, R.A.M.C. (ret.), died at Liphook, Hants, on April 7th, aged 89. He was born on March 1st, 1841, and was educated at Edinburgh, where he graduated as M.D. in 1863, also taking the M.R.C.S. in the same year. Entering the Army as an assistant surgeon on September 30th, 1864, he became surgeon major after twelve years' service, and, after being on half pay from December 3rd, 1880, to November 29th, 1881, retired on October 14th, 1885, with an honorary step as brigade surgeon. He served in the Sudan campaign of 1885, with the Nile expedition, when he was in charge of the field hospital at Dongola, and received the Egyptian medal with a clasp and the Khedive's bronze star. During the old regimental days he served in the 1st Foot, the Royal Regiment or Royal Scots; and in the 53rd Foot, now the King's Shropshire Light Infantry.

Lieut.-Colonel William Henry Cazaly, Indian Medical Service (ret.), died at Earl Soham, Suffolk, on April 10th, aged 56. He was born on September 24th, 1873, was educated at Bart's, and took the M.R.C.S. and L.R.C.P.Lond. in 1893; he graduated as B.A. of London University in 1892, and as M.B. and B.S. in 1895; he also took the D.P.H. of the London Colleges in 1910. Entering the I.M.S. as lieutenant on June 28th, 1900, he became lieutenant-colonel on December 28th, 1919, and retired on March 14th, 1920. He took part in the war of 1914-19, serving in France and Belgium in 1914-15.

Obituary.

ROBERT BRIDGES, O.M., D.Litt., LL.D., M.B., F.R.C.P.,

Poet Laureate; sometime Physician to the Great Northern Hospital, and Assistant Physician to the Hospital for Sick Children.

ROBERT SEYMOUR BRIDGES was born at Walmer on October 23rd, 1844, and died at Chilswell House, Boar's Hill, Oxford, on April 21st, 1930. From Eton he went to Corpus Christi College, Oxford, where he made a name as an oar-man, and graduated B.A. with a second in "Greats." After leaving Oxford he travelled abroad, and then entered as a student at St. Bartholomew's Hospital. He obtained his M.B. degree in 1874, and, having served as house-physician, was appointed casualty physician at St. Bartholomew's. Later he was elected assistant physician to the Great Northern Hospital and to the Hospital for Sick Children, Great Ormond Street. Thus, unlike Keats, who was poor and yet abandoned medicine after obtaining a licence to practise, Robert Bridges, with ample means, took his profession seriously during early manhood.

His strictly medical writings were few, but in other directions his pen was not idle, and until he finally retired from practice at the age of 37 his artistic growth was steadily proceeding in the background of his professional life. He made two contributions to the *St. Bartholomew's Hospital Reports*, one a note on a case of severe rheumatic fever treated with splints, and the other a remarkable paper entitled "An account of the casualty department," published in 1872, describing the medical work of the old surgery at St. Bartholomew's, where he acted as joint "filtrator," of out-patients from 9 o'clock to 12 noon, spending (as he found) a minute and a quarter over each case. His answers to the pertinent questions that arose in his mind give a vivid picture of the old casualty department and its work half a century ago. Feeling the responsibility and difficulty of filtering some 30,000 patients a year, of whom more than two-thirds were new cases, Dr. Bridges made a system of hieroglyphic notes, checking off each case as he dismissed it, and these records formed the statistical basis of his paper. Not until 1922, forty years after relinquishing his hospital appointments, did he write again on a medical subject. On that occasion he collaborated with Dr. Cuthbert Morton in an essay on the language of anatomy, published by the Clarendon Press as S.P.E. Tract No. IX. The authors' object was "to condemn the action of those who are moving to introduce a formal Latin international terminology into the British schools of anatomy, on the false notion that it will be of service to international science." Here it may be noted that the Poet Laureate was one of the founders of the Society for Pure English, and acted as general editor of its series of tracts.

This is not the place to appraise the poetry of Robert Bridges or his services to literature at large. His last and perhaps greatest work, *The Testament of Beauty*, which appeared only six months ago, on his eighty-fifth birthday, revealed again the perennial vigour of his mind, the wide range of his sympathies, and his mastery of metrical composition. He never for a moment wrote down to the public, but gradually his fame spread to wider circles. While there is little direct relationship between his medical studies and the character of his poetry, there are many traces in his poems of a penetrating insight into human nature acquired in the practice of medicine.

Many academic distinctions were conferred on him by his own and other universities, and the Royal College of Physicians of London elected him into its Fellowship in 1900. In 1913 his position in the world of letters was recognized by appointment to the vacant post of Poet Laureate. His last honour was admission to the Order of Merit. On his eightieth birthday a group of friends and admirers (of whom the late Editor of this *Journal* was one) gave him a clavichord. Our portrait shows him seated at the instrument; it was taken by Lady Gosse and engraved by Sir Hubert Herkomer, R.A., R.W.S., R.P., R.I., R.B.A., R.E., Litt.D., LL.D., Professor of Fine Art in the University of Oxford, Slade Professor of Fine Art in the University of Cambridge, Member of the Royal Academy of Arts, Berlin, Member of the Royal Academy of Arts, Munich, Member of the Royal Academy of Arts, Vienna, Member of the Royal Academy of Arts, Rome, Member of the Royal Academy of Arts, Amsterdam, Member of the Royal Academy of Arts, Belgium, Member of the Royal Academy of Arts, Stockholm, Member of the Royal Academy of Arts, Copenhagen, Member of the Royal Academy of Arts, Madrid, Member of the Royal Academy of Arts, Lisbon, Member of the Royal Academy of Arts, Buenos Aires, Member of the Royal Academy of Arts, Rio de Janeiro, Member of the Royal Academy of Arts, Montevideo, Member of the Royal Academy of Arts, Mexico, Member of the Royal Academy of Arts, Havana, Member of the Royal Academy of Arts, Caracas, Member of the Royal Academy of Arts, Bogotá, Member of the Royal Academy of Arts, Quito, Member of the Royal Academy of Arts, Lima, Member of the Royal Academy of Arts, Santiago, Member of the Royal Academy of Arts, Valparaiso, Member of the Royal Academy of Arts, Montevideo, Member of the Royal Academy of Arts, Buenos Aires, Member of the Royal Academy of Arts, Rio de Janeiro

MALCOLM HUTTON, M.A., M.B.,
Barrowden, Stamford.

WE regret to record the death of Dr. Malcolm Hutton on April 7th, at the age of 49. Malcolm Hutton was born in Oban, Argyllshire, and studied at Glasgow University, where he took degrees in arts, science, and medicine. After qualifying he acted as house-physician at the Western Infirmary, Glasgow, and as house-surgeon at the Royal Infirmary, Maternity Hospital, and Ophthalmic Institution. In 1908 he took the diploma in public health at Manchester University, and shortly after became medical officer of health for the district of Crompton. He practised first in Shaw, Lancashire, and later in Barrowden, Stamford. From 1914 to 1916 he was secretary to the Oldham Division of the British Medical Association. Dr. Hutton is survived by his wife, who is also in the medical profession, and three daughters.

Dr. A. Vernon Davies, M.P., writes:

The tragically sudden death of Dr. Malcolm Hutton, upon the eve of his retirement from practice, has come as a shock to those who knew him. His family removed from Barrowden at the end of February, while he remained for a few weeks to introduce his successor. He had an attack of influenza, which he tried to overcome whilst carrying on his work. He went to his new home in Devonshire on March 15th, seriously ill. Acute tuberculosis of the lungs developed, and he died from heart failure in a sanatorium on April 7th.

I had the privilege of knowing Hutton as a friend and fellow practitioner in Shaw (Lancs) for twelve years; and as a friend for another eleven years. He was the senior partner in a large industrial practice. In 1914 his partner "joined up" for the duration of the war. Shortly afterwards three other medical men from Shaw joined the R.A.M.C., so that for a long time three men were left to do the work which had been done formerly by seven. During this period Hutton worked, literally, day and night, with the result that at the end of the war he was a tired man—showing evidence of the great strain he had undergone. He left Shaw in 1919 for a country practice, but, as far as I could judge, still worked very hard—although, perhaps, in more congenial surroundings. But, like so many of our profession, he was fated to die "in harness." Hutton was a man of high intellectual capacity. He held degrees in arts, science, and medicine, and a diploma in public health. The last he obtained whilst working hard in practice at Shaw. He had the dual personality of the student and of the man of affairs—a rare combination, I think, in our profession. He was a great reader of our best literature; he kept himself abreast of all recent medical knowledge and was always seeking "new worlds to conquer." He took up ophthalmology as a new line during his country practice, and yet in spite of his devotion to learning he was at all times the painstaking, practical, level-headed Scot. When he served on the local medical war committee his judicial outlook and sound common sense were of great help to his colleagues in selecting the civilian medical practitioners to supply the needs of the Army. These attributes were recognized again by his colleagues in Rutland later on when he was appointed chairman of the panel committee, and chairman of the county insurance committee. He was a worker with a very methodical mind, which enabled him to get through an enormous amount of work. Conscientious to a degree, hating "sham" and hypocrisy, yet kind and tolerant when necessary, a friend and helper of the poor and needy, and a deeply religious man, Hutton, by his outstanding personality, his skill and ability, stands out as an example of the highest type of "G. P." He has left with his friends and patients a sweet memory of affection, respect, and admiration.

MR. H. PERCY ADAMS, F.R.I.B.A., who died recently at the age of 64, was well known to the medical profession inasmuch as he had for many years given special attention to the designing of hospitals in which he was an acknowledged master. He contributed an article to the Hospital Number of the *British Medical Journal*, of June 20th, 1925, on the construction of cottage hospitals, in which he gave a full description of the Woburn Cottage Hospital designed by him for the Duke of Bedford. Mr. Adams was the architect of the British Medical Association's central headquarters in the Strand, at the corner of Agar Street, which were occupied from 1908 till the removal to Tavistock Square in 1925.

The following well-known foreign medical men have recently died: Professor JULIUS RAECKE, head of the clinic for nervous diseases at Frankfort and author of a textbook on forensic psychiatry, aged 58; Dr. HERMANN FORTIG, extraordinary professor of genito-urinary diseases at Würtemberg University and head of the dermatological clinic at Würtemberg; Dr. CARLOS IBAN DE LA SIEVRA, founder of the medico-legal institute at Santiago; Dr. LÉON BLUM, professor of medicine at Strasbourg University, aged 52; Dr. EUSEBIO A. MORALES, one of the founders of the Republic of Panama, as the result of a motor accident; and Dr. ALBERT THÉVENOD, a paediatrist of Geneva, aged 32.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT rose on April 17th until April 29th. On April 15th it was announced that the first business of the House of Commons after the adjournment will be to discuss the Ministry of Health Estimates, with special regard to the administration of the National Health Insurance Act and recent charges of laxity. Poor Law administration and task work are also to be debated.

During the debate which preceded the Eastertide adjournment of the House of Commons on April 17th Mr. Adamson announced that April 1st, 1931, would be retained as the date on which the leaving age for pupils at elementary schools in Scotland would be raised to 15 years. On the same day the House of Lords decided not to insist on its amendment restoring desertion as a capital offence under the Army and Air Force (Annual) Bill. The Commons had disagreed with this amendment.

On April 17th a new writ was authorized in the House of Commons for a by-election in the West Fulham Division, Dr. G. E. Spero, who was returned for that constituency at the General Election, having retired.

The Hours of Industrial Employment Bill, "to regulate the hours of work in industrial undertakings," was presented in the House of Commons by Miss Bondfield on April 16th.

Road Traffic Bill.

When the Road Traffic Bill was before the House of Lords Clause 36, which deals with requirements in respect of policies to be taken out by motorists against third-party risks, was amended by the insertion of a new subsection running:

(2) Where any payment is made by an authorized insurer under a policy issued under this part of this Act in respect of the death of or bodily injury to any person arising out of the use of a motor vehicle on a road and the person who has so died or been bodily injured has to the knowledge of the authorized insurer received treatment in a hospital in respect of the fatal or other bodily injury so arising, there shall also be paid by the authorized insurer to such hospital the expenses reasonably incurred by the hospital in affording such treatment to an amount not exceeding twenty-five pounds for each person so treated.

A standing committee of the House of Commons is now examining the same bill, and reached Clause 36 on April 10th. Mr. REMER moved to leave out Subsection 2, as set out above.

Mr. MORRISON (Minister of Transport) said he and the committee were agreed on the financial difficulties of the hospitals, and on the fact that they were faced with a problem in handling the accidents associated with motors. On the other hand, as one who believed that all health services should be public, he was bound to say that the only proper way to run them was on the basis of public services by public authorities. The present admitted difficulties of the hospitals might not then arise. In his view Subsection 2 was alien to the main purpose of this part of the bill, which was to ensure that the legal claim to compensation by a third party for death or injury should not be defeated by the financial insufficiency of the motorist. The subsection was illogical, and would be haphazard in effect, awkward to work, and largely ineffective. Hospital authorities would be unable to recover their expenses unless they were in a position to notify the insurer that the injured person had been treated in that hospital, and the insurance companies would probably take steps to prevent the fact of treatment in a hospital being brought to their notice. On the other hand, members of the committee were receiving numerous com-

munications, and might desire that something should be done on the lines of the subsection. He advised the committee that hospitals ran some risk of motorists inclining to decrease their contributions to hospitals because part of their insurance money could be compulsorily taken by the hospitals. The hospitals declined the obvious and logical course of establishing a legal claim against the patient because that would interfere with their voluntary character. He understood that hospitals could not claim now, but he would be disposed to give them the legal right to say that in cases arising out of street accidents they would require payment unless the person treated could not afford to pay. That was the position of the municipal hospitals under the Local Government Act of 1929, but he gathered that the voluntary hospitals did not desire it. He indicated amendments which he was prepared to accept to make the subsection more workable.

Colonel ASHLEY argued that the subsection was fair and workable.

Dr. SALTER said the larger hospitals in London were not put to greater expense by motor accidents than they were in the old days of horse traffic. Provincial hospitals were hit hard by admission of reckless drivers and others involved in motor accidents. Every day the provincial hospitals found it difficult to get payment of the cost of treating these patients.

Mr. MORRISON intervened to say that the motorist involved in an accident would get no benefit from the insurance company. Neither he nor the insurance company would be under an obligation to pay the hospital for his treatment.

Dr. SALTER said the hospitals were aware of this. The clause did not go as far as they would have liked, but it did make a beginning. The returns received by the Hospitals Association showed that the amount repaid for treatment of motoring accident cases was about one-tenth. Leeds General Hospital admitted 544 cases at a cost of £3,575, and £243 was repaid; North Staffs General Hospital spent £2,365 and recovered nothing; Bradford Royal Infirmary recovered £65 out of £1,173; Blackburn Royal Infirmary recovered nothing out of £1,003, and so on. In many of the small cottage hospitals the position was worse, and up to 33 per cent. of the beds might be at one moment occupied by cases of motor accidents. At Cardiff, in every case, patients were interviewed, and a written undertaking obtained to include hospital costs in any claim made against the insurance company, but only £130 was recovered out of £3,035. Actuarially, between 1s. and 2s. addition to the present premium would cover the new liability which this subsection would impose on the insurance companies.

Major HILLS advocated a direct levy on the motorist's licence for the benefit of hospitals. One penny per vehicle would bring in £10,000 a year.

Sir JOSEPH LAMB said the hospitals of Outer London were much affected by the question.

Mr. MORRISON remarked that the committee advanced the doctrine that every person treated in a voluntary hospital ought to pay. That was a new doctrine. Let the voluntary hospitals recognize that as a new state of things and inconsistent with the voluntary system. Even after this subsection had been carried only the minority of motor cases would be covered.

Dr. SALTER: The estimate is one-third.

Mr. MORRISON pointed out that the insurance companies and the motoring associations had not circularized members against the subsection. He could not fight for people who would not fight for themselves.

By 20 to 10 the committee voted for the retention of Subsection 2.

On the motion of Sir JOSEPH LAMB, the committee added at the end of the subsection the words:

"For the purposes of this subsection the expression 'hospital' means an institution which provides medical or surgical treatment for in-patients, and the expression 'expenses reasonably incurred' means, in relation to a person who receives treatment in a hospital, an amount for each day such person is maintained in such hospital representing the average daily cost per patient of the maintenance of the hospital and the staff thereof and the maintenance and treatment of the patients therein: provided that the subsection shall not apply to any case where a charge has been made by the hospital in respect of such treatment."

Minor amendments were made to extend the obligations of the subsection to motorists who, instead of taking out a third-party insurance, give a surety or make a deposit. Clause 36 was then added to the bill.

Radium: Application for Special Powers Approved.

Resuming a discussion in the previous week of the proposal by the Hull Corporation to become radium trustees, a Local Legislation Committee of the House of Commons had before it, on April 15th, a compromise on the subject which had been approved by the Ministry of Health. The corporation had asked for certain powers on the ground that at present the radium in its possession could not be used to its fullest advantage. The clause originally proposed by the corporation ran: "The corporation may provide and supply (with or without charge therefor) to any medical practitioner, medicines, appliances, and requisites for the care and surgical treatment of sick persons, or may contract with any person to provide and supply the same. The corporation may purchase or hire or enter into any agreement or arrangement for the use of radium, and may provide suitable appliances for its reception, storage, and use."

Mr. E. WOOLL, appearing for the corporation, said negotiations had been proceeding steadily since the committee adjourned, and the problem had been approached from a different angle. The new provision for which the corporation asked sanction was:

"(1) The corporation shall have power to make reasonable subscriptions or donations to any trustees or other body constituted for the purpose of holding, supplying, or administering radium, and on making any subscription or donation under this section the corporation may impose such terms and conditions relative to the supply, administering, and use of radium as they may think fit.

"(2) Any expenditure under this section shall not exceed in any one year an amount equal to that which would be produced by a rate of one penny in the pound on the property liable to be assessed for the purpose of the general district rate."

Mr. Wooll said this provision was approved by the Ministry of Health.

The committee approved the amended section.

National Health Insurance.

On April 15th Miss LAWRENCE told Sir F. Hall that, according to a report recently furnished by the Government actuary of the sickness and disablement benefit experience of a representative sample of the whole body of insured persons, the number of insured men per 100 who claimed sickness benefit in 1921 and 1927 was 14 and 23 respectively. The amounts expended under the Health Insurance Acts in England and Wales in 1921 and 1927, in respect of sickness benefit, were £7,176,800 and £11,818,000; of disablement benefit, £2,639,600 and £5,358,000; and of medical benefit, £9,334,800 and £8,772,500. In this connexion it was pointed out that the increase in the amounts expended on sickness and disablement benefits in 1927, compared with the corresponding amounts expended in 1921, was to some extent due to the fact that in the later of those years there were larger increases in the benefit rates under the societies' schemes of additional benefits. The cost per head of the population of England and Wales in 1921 and 1927 for national health insurance was 3s. 11d. and 4s. 8d. respectively, and of medical benefit provided under the Health Insurance Acts 4s. 11½d. and 4s. 5½d. The factors which had contributed to the increases above noted were numerous and complex, and without further and fuller consideration the Minister of Health did not think it possible to make any general statement as to the relation between those facts and the increased provision of curative and preventive treatment.

Vaccination.

In a reply to Mr. Freeman, on April 10th, Mr. GREENWOOD stated that 237,627 certificates of successful primary vaccination of children under 14 years of age and 267,044 statutory declarations of conscientious objection were received by vaccination officers in England and Wales during 1929. During the same period, among children under 14 years of age, 12 deaths occurred which were classified to small-pox and 16 deaths in which the words "vaccination," "vaccinia," or "post-vaccinal encephalitis" appeared in the medical or coroner's certificate. Eleven other cases of children under 14 years of age were brought to the notice of the department, in which death occurred within four weeks of vaccination. In at least 8 of these cases there was no reason to think that vaccination contributed in any way to the fatal issue.

Miss LAWRENCE, on April 15th, told Mr. Freeman that under the Vaccination Acts certificates of postponement of vaccination must be given in the case of infants which were not in a fit state to be vaccinated. The instructions to public vaccinators emphasized that only infants in a fit state of health must be vaccinated. The Minister of Health saw no reason, therefore, to arrange for an independent medical examination for infants before being compulsorily vaccinated.

Psittacosis.—Miss LAWRENCE told Mr. West Russell, on April 16th, that the Ministry of Health had received information of 80 cases of illness which commenced during 1930 and in which the patients had been associated with sick parrots. Thirteen of these cases had proved fatal. The Minister could not say definitely how many had suffered from psittacosis, but in nine of the cases psittacosis appeared on the certificate as a cause of death. Mr. Greenwood was satisfied that adequate steps had been taken to deal with the matter.

Silicosis.—Mr. CLYNES told Mr. Hollins, on April 10th, that the amendment of the Various Industries (Silicosis) Order to include cases of partial incapacity was dependent on the passage of the bill which the Government had introduced to amend the provisions of the Act which relate to medical arrangements for examination and diagnosis. The bill had been read a second time in the House of Lords, and it was his intention, as soon as it had passed, to take up the question of the amendment of the Order.

Fibrosis of the Lungs.—Mr. CLYNES, in reply to Mr. Morley on April 10th, said that the question of scheduling the disease of fibrosis of the lungs under the Workmen's Compensation Act was one on which further research was necessary, and at his request the Medical Research Council had set up an expert committee to institute and co-ordinate research into the subject. The committee was at work, and would proceed as expeditiously as possible, but no early results could be expected.

Deaths due to Cancer in Scotland.—Mr. JOHNSTON told Mr. F. Owen, on April 14th, that 5,291 deaths registered in Scotland in 1915 were classified as being due to cancer. In 1929 the number of such deaths registered was 7,108.

Leprosy in India.—On April 14th Mr. BENN, replying to Mr. Granville, said that he had had no reports, since the last census, of the number of lepers in India, and there was no reliable information available. The provincial Governments were all in touch with the India Council of the British Empire Leprosy Relief Association. They received grants from the association approximately in proportion to the subscriptions of each province to its central fund.

Tannic Acid Treatment of Burns.—Mr. SHORT informed Dr. Vernon Davies, on April 9th, that the conclusion reached in the report of the senior medical inspector concerning the tannic acid treatment of burns was that it was not suitable generally for the first-aid treatment of burns at a factory or workshop. It could only be properly given in works where there was a suitably equipped ambulance room in charge of a properly qualified person, and in the treatment of minor burns it had no advantage over sterilized burn dressings. In the case of severe burns it might be valuable where the patient could not be moved to hospital without considerable delay, but otherwise the protection of the burn by a simple dressing was the proper procedure. He did not, therefore, advise any modification of the existing instructions. Dr. Davies thereupon pointed out that a very large body of medical opinion totally disagreed with the advice given.

Tuberculosis in the Navy.—Mr. MOSES asked, on April 16th, what steps were taken to minimize tuberculosis as a cause of invaliding from the Navy, and whether better conditions of service were under consideration to arrest the increase of tuberculosis which was taking place. He alleged that a large percentage of engine-room artificers were being invalided for that disease. Mr. A. V. ALEXANDER replied that the incidence of tuberculosis in the Navy was not unduly high, nor was it appreciably higher among engine-room ratings than in the seaman branch. Precautions to minimize the causes of tuberculosis were under constant review.

Burntwood Mental Hospital.—In reply to Mr. McShane, on April 10th, Mr. GREENWOOD gave the following table concerning Burntwood Mental Hospital. During 1929 there was one resident medical officer to 310 patients.

Year.	Daily Average No of Patients Resident	No. of Admissions.	No. of Deaths.	Year.	Daily Average No. of Patients Resident.	No of Admissions.	No. of Deaths.
1920	882	250	111	1925	9'4	197	71
1921	890	242	106	1926	926	194	87
1922	858	223	86	1927	919	196	109
1923	868	226	81	1928	930	219	1'4
1924	902	201	72	1929	931	207	92

The number of patients in institutions for the insane and mentally defective were as follows:

Year.	In Institutions for the Insane.			In Institutions for Mental Defectives.
	Certified Patients.	Voluntary Boarders.	Total.	
1921 . .	99,751	261	100,012	11,675
1922 . .	103,071	292	103,363	13,394
1923 .	105,821	338	108,159	15,327
1924 ..	109,785	510	110,295	17,104
1925 ..	111,199	6 5	111,824	18 735
1926 ..	113,542	695	114,237	20 297
1927 .	116 375	795	117,171	21,662
1928 . .	118 327	879	119,206	22,812
1929 . ..	121 333	1,006	122,339	24,207
1930 ..	122,902	1,020	123,922	25,697

Vitacream.—Mr. GREENWOOD said, on April 10th, in reply to Mr. Hanbury, that he was aware of the sale of vitacream, which was seriously competing with genuine British cream, but he could not at present introduce legislation so that it should be sold under the designation of cream substitute, with an analysis shown clearly.

Traffic in Dangerous Drugs.—Replying to Mr. Mander, on April 10th, Mr. CLYNES said the Council of the League of Nations had not yet considered the report of the Advisory Committee on Traffic in Opium and other Dangerous Drugs. The responsibility for putting a stop to illicit traffic in drugs would rest on the Governments in countries where it took place, and he presumed the Council would wish to know what action had been taken when the report came before them.

Indian Medical Degrees.—Mr. BENN told Major Pole, on April 14th, that the Government of India made proposals for a provisional arrangement for guaranteeing Indian medical degrees, pending the introduction of legislation in the Indian Legislative Assembly to establish an All-India Medical Council, but these proved unacceptable to the General Medical Council. It had made no further proposals since the decision of the General Medical Council to discontinue recognition.

Royal Naval Medical School, Greenwich.—On April 15th Mr. AMMON, replying to Dr. Vernon Davies, said that there would normally be two courses a year at the Royal Naval Medical School, Greenwich, for acting surgeon lieutenants, but these were at present in abeyance. There were also normally two courses a year for surgeon lieutenant commanders. The maximum number of students who could be trained at any one time at the school was twelve officers and twelve ratings. The approximate amounts included in the estimates for the Royal Naval College, Greenwich, which could be attributed to the medical school, were, in 1928, £9,650; in 1929, £9,800; and in 1930, £9,800. These amounts represented the cost not only of the above-mentioned courses of instruction, for which separate figures were not available, but also of a very large amount of highly technical work of the greatest importance to the health of the Navy.

Army Rejections.—In a table supplied to Major Glyn, on April 16th, Mr. SHAW gave ratios per 1,000 candidates for Army enlistments who were rejected for the following physical defects in 1910, 1921, and 1929:

Diseases of the middle ear	6.35	11.71	50.21
Loss or decay of many teeth	55.95	35.16	26.13
Defects of lower extremities...	18.74	11.58	33.73
Defective vision	18.15	58.39	26 69
Diseases of the heart	40.38	37.87	43.53
Insufficient weight	5.34	11.89	24.50
Flat-feet	10.44	27.22	16.90
Under chest measurement	43.97	33.39	10 8

Foreign Medical Men and the Post-Graduate Hospital and Medical School.—Replying to Mr. Matters, on April 15th, Mr. GREENWOOD said that the granting of medical degrees did not rest with the Ministry of Health. Consideration of facilities whereby foreign medical men and women might secure, in connexion with the British Post-Graduate Hospital and Medical School, a British post-graduate degree supplementary to and based on recognition of the diplomas secured by them in their own countries would appear to be premature pending the establishment of the hospital and of the medical school.

Beds Available for Treatment of Phthisis in Kent.—Answering Captain Balfour, on April 17th, Mr. GREENWOOD said the average number of beds available in the year 1929–30 under the scheme of the Kent County Council for treatment of pulmonary tuberculosis was 364, of which 155 were in institutions provided by the county council. The numbers of persons suffering from pulmonary tuberculosis awaiting admission to residential institutions were 74, 60, and 72 on January 1st, February 1st, and March 1st respectively. The number so waiting had been reduced to 50 on April 1st. The proportion that number bore to the number of available beds was slightly higher than for the country as a whole, but the average waiting period in Kent was approximately one month. The county council proposed, as a temporary measure, to reduce the waiting list by the use, for suitable cases, of accommodation in the Poor Law institutions which were transferred to them on April 1st.

Chinese Eggs.—In a reply to Mr. Ramsbotham, on April 17th, Mr. GREENWOOD said that so far as he knew the imports of liquid and dried eggs from China were free from contamination, and if in good condition were without danger to the public health. They were required to be free from preservatives, and, in common with other imported foods, were subject to inspection at the port of entry, and might be seized and destroyed if found to be unsound, unwholesome, or unfit for human consumption. The value of such eggs imported from China during 1929 was £3,574,640. These eggs were mainly used by the baking trade for cake making.

Inspection of Cattle for Tuberculosis.—In a reply to Mr. Smithers, on April 17th, Mr. GREENWOOD asserted that an increasing number of local authorities are carrying out regular veterinary inspections of cattle and having samples of milk tested for tubercle bacilli, with a view to the exercise of their powers under the Milk and Dairies Act. He did not propose to introduce any further legislation on this subject at present, but was in consultation with the Minister of Agriculture and Fisheries, with a view to the issue of a circular to local authorities indicating further steps which they might advantageously take under existing powers. For this purpose he would have regard to the views of the medical and veterinary advisers of the two departments, as well as those of other members of the two professions.

Pensions Cases.—Mr. ROBERTS stated, on April 17th, that at the end of March, apart from cases of mental affliction in public institutions, approximately 4,700 patients were in hospitals belonging to the Ministry of Pensions, or in hospitals where accommodation was secured at a capitation rate. The hospital population fluctuated considerably in the year, the aggregate number of discharges, about 18,000, being slightly in excess of the number of admissions. No change in the use of the Ministry's hospital at Orpington was at present contemplated.

Notes in Brief.

On April 14th Mr. Clynes informed Mr. Mander that the decree of the French Government providing for direct limitation of the manufacture of narcotic drugs was gazetted in the *Journal Officiel* of March 25th.

Medical News.

THE Oliver-Sharpey lectures before the Royal College of Physicians of London will be delivered by Professor J. J. R. Macleod at the College, Pall Mall East, S.W.1, on Tuesday, April 29th, and Thursday, May 1st, at 5 p.m. The subject of the lectures is diabetes as a physiological problem. They are open to members of the medical profession on presentation of visiting cards.

THE annual meeting and luncheon of the Tavistock Square Clinic for Functional Nervous Disorders will be held at the Wharncliffe Rooms, Hotel Great Central, on Monday, May 5th. The Chairman of Council, Dr. H. B. Brackenbury, will open the proceedings at 12.15 o'clock, luncheon will be served at 1 o'clock, and after speeches by Sir Farquhar Buzzard and Miss Isobel MacDonald the honorary director (Dr. H. Crichton-Miller) will give an account of the year's work.

THE annual meeting of the Medical Mission Auxiliary of the Church Missionary Society will be held in the Central Hall, Westminster, S.W., on Wednesday, May 7th, at 7.15 p.m. The chair will be taken by Lord Lloyd, and among the speakers will be Dr. H. Gordon Thompson, formerly of Hangchow Hospital. Tickets of admission may be obtained from the superintendent, Loan Department, Church Missionary Society, Salisbury Square, E.C.4. A small number of reserved seats are available at one shilling each.

THE eighty-third half-yearly dinner of the Aberdeen University Club, London, will be held at the Trocadero Restaurant on Thursday, May 15th. The chairman will be Professor J. J. R. Macleod, and the guest of the club Professor Leonard Hill. The honorary secretary's address is 9, Addison Gardens, W.14.

THE annual dinner and meeting of the University of London Medical Graduates' Society will be held at the Langham Hotel, Portland Place, W., on Tuesday, May 13th, at 7.45 p.m. The President, Sir StClair Thomson, will be in the chair. Applications for tickets (price 10s. 6d.) should be sent to the honorary secretaries of the society, 11, Chandos Street, Cavendish Square, W.1.

A PUBLIC conference on by-laws under Section 5 of the Public Health (Smoke Abatement) Act, 1926, will be held under the auspices of the National Smoke Abatement Society, on Friday, May 2nd, at 71, Eccleston Square, Westminster, at 3.30 p.m. Mr. C. J. Allpass, chairman of the Greater London Regional Smoke Abatement Committee, and of the Public Control Committee of the London County Council, will open the discussion.

A POST-GRADUATE lecture entitled "Radium in cancer" will be given at the University of Sheffield, physics department, on Tuesday, May 6th, at 8.45 p.m., by Dr. J. Murdoch, chief of the department of radium and radiotherapy, Brugmann Hospital, Brussels, and director of the cancer centre of the University of Brussels.

UNDER the auspices of the British Institute of Philosophical Studies, Professor Lascelles Abercrombie will deliver a course of six lectures on aesthetic philosophy, commencing on Monday, May 5th, at 5.30 p.m. Further information may be obtained from the Director of Studies of the Institute, 88, Kingsway, W.C.2.

IN aid of King Edward's Hospital Fund for London a series of six "cross-examinations," in which various well-known persons will be charged with offences they are alleged to have committed, will be held at the London School of Economics, Houghton Street, Aldwych, each Tuesday, at 5.30 p.m., beginning on April 29th. At the first cross-examination Mr. Low, the cartoonist, will be charged with libelling politicians, Mr. A. P. Herbert taking the part of prosecutor, and Mr. W. Pett Ridge of judge. Tickets (7s. 6d., 5s., 3s. 6d., and 2s. 6d. each, or £2, £1 5s., 18s., and 12s. 6d. for the series) may be obtained from the secretary, King Edward's Hospital Fund for London, 7, Walbrook, E.C.4, or at the doors.

THE centenary of the birth of the celebrated surgeon Richard von Volkmann, who was one of the founders of the German Society of Surgery, and died in 1889, will be celebrated at Halle on April 27th, when addresses will be given by Professor Voelcker and the President of the society.

PROFESSOR FRANCIS FRASER'S address entitled "Before the Finals and After," given to senior students and recently qualified practitioners at a reception organized by the Metropolitan Counties Branch of the British Medical Association, was reported in the *Supplement* to our issue of February 22nd, and the full text has now appeared in the April issue of the *St. Bartholomew's Hospital Journal*.

THE fifty-fourth Congress of the German Society of Surgery is being held at the Langenbeck-Virchow House, Berlin, from April 23rd to 26th, under the presidency of Professor W. Anschütz of Kiel.

THE twenty-first congress of the German Roentgen Society will be held in Berlin from April 27th to 29th, when the following subjects will be discussed: intravenous pyelography, introduced by von Lichtenberg of Berlin, and the present methods of irradiation of cancer, introduced by Miescher of Zürich, Holfelder of Frankfort, and Schinz of Zürich.

THE date of the second International Paediatric Congress at Stockholm has been advanced one day, and will cover the period August 18th to the 21st. The Swedish organization committee has chosen for discussion: the biological effect of direct and indirect ultra-violet irradiation; the physiological and pathological significance of the thyme-lymphatic system; and the psychology and pathological psychology of childhood, their significance as a branch of paediatric research and teaching, and their application in medico-social work. The fee of admission is 20 Swedish crowns for regular members, and 10 crowns for members of their families. Facilities are being arranged for excursions after the congress to various places of interest in Sweden. A booklet entitled *Summer in Sweden* can be obtained from the Swedish Organization Committee.

THE library of the Royal Society of Medicine is now open until 10 p.m. every Thursday in addition to being open to this hour on Tuesdays and Fridays. Hitherto Fellows resident outside the London postal area have enjoyed the privilege of having books sent to them from the library carriage paid. This privilege has now been extended to all Fellows not resident or practising within a mile of the Society's house.

ON March 3rd, the twenty-fifth anniversary of the discovery of *Spirochaeta pallida*, the Fritz Schaudinn medal was awarded by an international committee of the Hamburg Institute for Tropical Diseases to Professors M. Hartmann of Berlin, F. d'Hérelle of Paris, and E. Bechenow of Hamburg, in recognition of their microbiological researches.

IN the April issue of *The World's Children*, a monthly journal of child care and protection considered from an international point of view, are published two articles of medical interest: "For the children of Greece," an account by Mr. H. D. Watson, of the Athens Eye Clinic, devoted mainly to the treatment of trachoma; and "In the Welsh Marches," a description of the recently developed scheme of ante-natal work in Monmouthshire. *The World's Children* may be obtained from the Weardale Press, Limited, 26, Gordon Street, London, W.C.1, price 4d.

THE April issue of the *Leprosy Review* contains an interesting article by Dr. H. W. Wade, describing the growth of the anti-leprosy campaign in the Philippine Islands. The Philippine system combines segregation of infectives near their homes, when possible, with dispensary treatment of early cases, and intensive survey and educational work. Other articles in this issue deal with work on the Gold Coast and in Norway, and there is an account of leprosy of the nose and mouth. The *Review* may be obtained from the office of the British Empire Leprosy Relief Association, 29, Dorset Square, N.W.1, price 2s.

AN article by Dr. T. Wilson Parry entitled "Holes in the skulls of prehistoric man and their significance," has been reprinted from the *Archaeological Journal*, 1922. Dr. Parry discusses the five chief causes of these holes, and gives illustrations of their incidence. The subject-matter is illustrated by numerous reproductions of photographs of such skulls.

THE Alexander Pedler Lecture for 1929, under the auspices of the Manchester Literary and Philosophical Society and the British Science Guild, was delivered by Dr. G. C. Simpson, F.R.S. In considering his subject, "Past climates," from a meteorological point of view Dr. Simpson remarked that while all meteorologists accepted certain geological evidence of radical differences in present and past climates they disagreed, as did the geologists, in explaining how these changes had been brought about. The problem of past climates was to determine what changes in the existing conditions would produce the climates which the geologists inferred from their observations. Present temperature distribution depended on the amount of solar radiation, the horizontal transfer of heat from one part of the earth to another, and on the characteristics of terrestrial radiation. How much did variation in each of these factors contribute to the observed climatic changes? Copies of the lecture may be obtained from the offices of the British Science Guild, 6, John Street, W.C.2, price 1s.

THE KING has confirmed the appointment of Dr. Lawson Gifford and Dr. Basil Mayor Wilson (superintending medical officer) to be nominated members of the Legislative Council of the Island of Jamaica.

THE late Sir Alfred Fripp has left estate of the gross value of £1,01,905, with net personalty £52,655.

DR. C. ZOELLER has recently been appointed professor of epidemiology and bacteriology at the Val-de-Grâce School of Military Medicine, Paris.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863*, and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 21361 Edinburgh).

QUERIES AND ANSWERS.

GRAMOPHONE RECORDS OF LECTURES.

"A. A. H." whose auditory memory is much better than his visual memory, inquires whether it is possible to obtain gramophone records reproducing medical lectures.

INCOME TAX.

Assistant Becoming a Partner.

"SIMPLE" acted as an assistant or locumtenent for nearly two years up to November 1st, 1928, when he became a partner (one fifth share) in the firm for which he was then working as an assistant. He did not buy any share in the book debts. In December, 1928, he paid £21 11s. 2d. as his share of the firm's assessment, and a similar amount in July, 1929. He also paid £7 11s. 8d. in January, 1929, in respect of his salary as assistant, presumably for the period April 5th to November 1st, 1928. On January 1st, 1930, he paid £57 13s. 9d., being a first instalment. His "total income from April, 19 8, to April, 1929, was £601." His firm's accountant says that the £57 13s. 9d. is based on what he earned between April, 1929, and April, 1930.

*** It is, of course, impossible to see what has been assessed without knowing precisely how the amount of the payments were calculated, but the position appears to be as follows: the £7 11s. 8d. covered our correspondent's liability in respect of his assistantship, and the other payments must refer to his income as a partner from November 1st, 1928, onwards. Apparently £43 2s. 4d. (that is, 2×£21 11s. 2d.) was calculated as his share of the assessment for the period to April 5th, 1929, and £115 7s. 6d., of which he has paid half, for the year to April 5th, 1930. When he has paid the second instalment he will have accounted for his liability "on what he earned between April, 1929, and April, 1930." But the assessment, of which he has to take his share, is based on the firm's previous year, and must include all receipts, whether paid to "Simple" or other persons, or alternatively must be based on bookings. Perhaps it will be clearer if it is borne in mind that if "Simple" had retired at April 5th, 1930, he would not have been liable to tax on his share of cash received—except, of course, that he would have to pay the second instalment of £57 13s. 9d.

Expenses of Consulting Practice.

"M.B." is a married woman living at home. She inquires whether certain expenses can be deducted.

*** The part-time expense of London consulting rooms is an admissible expense, but the expense of travelling from home to town is not admissible—like the City clerk's season ticket it has to be paid for out of taxed income, as part of the expense of living away from one's work. Subscriptions to societies: these depend on whether the society has made an arrangement with the Inland Revenue department; if a list is enclosed with the account no doubt the tax office dealing with the return will make the appropriate adjustments. No special claim is necessary for the £4 allowance due to married women against the assessment on their earnings, but it is advisable to see that it is given.

LETTERS, NOTES, ETC.

A BORROWED ARM.

MR. CHARLES W. CATHCART would be much obliged if the borrower of a Beaufort artificial arm will kindly return it to him at once, addressed Charles W. Cathcart, F.R.C.S., Royal Infirmary, Edinburgh.

ACCIDENTAL EVISCERATION OF THE EYEBALL.

DR. J. K. HOWLETT (East Dereham) writes: An energetic managing director of an amateur dramatic society, while hurrying in the dark through a cloak room to get back to a rehearsal, was caught by one of a row of hat pegs on a frame stand. The peg, which was of the nature of a double-wire hook 3/4 in. in width, penetrated the orbit and performed a complete evisceration of the eyeball. Beyond some injury to the lacrymal duct, there was no other damage. I took him immediately to the Norfolk and Norwich Hospital, where Dr. A. Greene performed a Mule's operation. I found the eyeball next morning hanging on the hat peg by the optic nerve, which was severed at slightly more than an inch from the eyeball.

PNEUMOCOCCAL CEREBRO-SPINAL MENINGITIS.

DR. A. MUIR CRAWFORD (Glasgow) writes: In the *Journal* of March 22nd (p. 576) Dr. A. S. Gubb reports a case of pneumococcal cerebro-spinal meningitis in which death occurred on the second day. The record of a similar case, but of shorter duration, recently seen by me in consultation, may be of some interest. A young man, aged 23, went to bed about 11 p.m., apparently in good health, but at 2 a.m. he awoke complaining of very severe headache; he was very restless, the headache became agonizing, and at 6 a.m. he was unconscious. Four hours later, when I saw him, he was still unconscious, and during examination he had several short attacks of extreme restlessness and rigidity. The pupils were equal and slightly dilated; they reacted to light. The limbs, especially the legs, were markedly rigid, but no definite rigidity could be detected in the neck. The knee-jerks were brisk, and Kernig's sign was positive. No abnormality could be detected in the heart, lungs, or abdomen. Lumbar puncture gave vent to a turbid cerebro-spinal fluid under increased pressure; a direct smear showed many pus cells and abundant pneumococci, and on culture a pure growth of the pneumococcus was obtained. The patient died about 12 noon, approximately ten hours after the onset of symptoms.

DYSENTERY SIMULATING APPENDICITIS.

DR. BHAGWAN RATTAN (Rupar, Punjab) writes: Dr. Julius Burnford's article on missed diagnoses (February 22nd, p. 327) reminds me of a case of appendicitis in which the actual cause was discovered only when dysenteric symptoms developed. The patient, aged about 25, was brought to me with all the symptoms of appendicitis—vomiting, rigidity of right rectus with tenderness over McBurney's point, and a rapid pulse. He gave a history of such attacks occurring every third or fourth month. The symptoms subsided after palliative treatment, and he was advised to consult a surgeon. Three days later he consulted me again. He was then suffering from amoebic dysentery, and was given two courses of emetine injections of six days each twice a day. The slight pain in the right iliac fossa that had persisted after the first treatment vanished after two days' emetine injections, and he has had no more attacks of appendicitis for fifteen months. I think the recurrent attacks of appendicitis were due to an amoebic ulcer in or near the appendix.

PRECISION IN PSYCHOLOGICAL TERMINOLOGY.

DR. ALAN MABERLY (Vienna) writes: I am glad to see articles, or reports of lectures, upon psychological topics appearing in the *British Medical Journal*, but may one not look for the same clarity of thought and precision of expression that one expects when more specifically "medical" subjects are being dealt with? In your report of Dr. Campbell McClure's lecture given before the Hunterian Society (March 29th, p. 609), the statement appears that a child's "instinctive reaction to fear is to lie." Surely all careful observation goes to show that this reaction, where it occurs, is a special adaptation to a particular type of unsympathetic environment. Were we to accept it as being instinctive (together with other similar reactions), it would be difficult to disagree with other statements in the same report. But I feel impelled to protest against the use of phrases such as "without probing in the mud that exists in the unused memory of most of us." I would also submit that ridicule, if "the most powerful weapon to use against the Englishman," is hardly the most scientific, and is as little likely to deter people from seeking the aid of the irregular practitioner as to assist the medical profession to "live down its reputation for pride and prejudice."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *200*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

Intracutaneous Vaccination.

373. F. KIENSTEIN and G. HUNACUS (*Med. Welt*, October 26th, 1929, p. 1539) performed intracutaneous vaccination on 62 healthy children aged from 4 months to 1 year and 10 months, and have come to the following conclusions. They find that intracutaneous vaccination is technically more difficult, takes longer to perform, and is more painful than the cutaneous method; it requires a special assistant for keeping the child still. At least one new tube of lymph has to be used for each case. Owing to the unsuitable for wholesale vaccination. The technique it is unsuitable for wholesale vaccination. The use of a sterile lymph, which is not method necessitates the always available in vaccine institutes, since it has not yet been ascertained whether the saprophytic bacteria present in most varieties of lymph are as harmless when injected intracutaneously as they are in ordinary vaccination. The necessary dilution of the lymph must depend on its virulence, which should be accurately known. Since the character of secondary infection is greater, owing to the character of the trauma and the more elaborate procedure, than in cutaneous vaccination, the responsibility for any complication must fall on the vaccinator. Intracutaneous vaccination may be regarded as successful if an infiltration of at least the size of a pea results; as the infiltration may not reach its full development until from seven to nineteen days after vaccination, the site should be inspected during this period. Since no scars are left when the vaccination pursues a normal course, it is impossible to tell subsequently whether the person has been successfully vaccinated or not. The only advantage of the intracutaneous over the cutaneous method is the avoidance of a scar, which may be of importance in the case of women. The intracutaneous method is absolutely contraindicated in skin diseases, especially eczema, for other writers recommend it, owing to the possibility of generalization of the vaccine virus through the blood stream. The present authors agree that the employment of intracutaneous vaccination on an extensive scale is to be deprecated because the danger of complications is much greater than with the ordinary method.

Human Brucella abortus Infection.

374. A. S. GIORDANO and R. LL. SENSENICH (*Journ. Lab. and Clin. Med.*, February, 1930, p. 421) record a study of 35 cases of *Brucella abortus* infection in man, 7 of which appeared in a preliminary report in 1927. Sex does not appear to be concerned, and occupation is an etiological factor only in so far as it provides opportunities for infections. The greatest age incidence is in the second, third, and fourth decades; the youngest patient was 16 and the oldest 61. The literature records no case below the age of 8, and this apparent immunity in children parallels that observed in young calves. The authors remark that the disease occurs much more frequently in small communities, since in these there are fewer pasteurization plants, and raw milk is more generally consumed. The incubation period is unknown, and could be approximately determined in only one case, and the prodromal symptoms vary considerably. An insidious onset with fatigue, anorexia, low fever, and headache, with muscular weakness or joint discomfort, is most common; chills are not usually the initial symptom. Rarely the onset is more abrupt, and evidences of sepsis are the first signs. Arthritis may be the earliest manifestation, or the first signs. Arthritis may be attacked with the occurrence of nervous system may be neuritis. The disease may be acute or chronic; it has been suggested that this tendency to acuteness or chronicity may have a diagnostic value, separating *Br. abortus* and *Br. melitensis* infection. According to the predominant symptoms and various tissues attacked, the disease may assume one or other of the following types: septic, arthritic, neural, visceral, and glandular. Fever is the most commonly present symptom, though chills are almost as constant. Sweats, which may be mild or profuse and offensive, occur with or independently of the chills and fever. Headache, usually occipital and occurring early in the disease, is constant and extremely distressing; it may be associated with backache. Arthritis and neuritis may occur at any stage, and may be of variable duration. Apart from anorexia and vomiting, gastrointestinal symptoms are uncommon. Orchitis and oophoritis are usually present, while unusual skin lesions may occasionally be seen. Renal and cardiac manifestations are infrequent, but pulmonary symptoms are common. Except for an initial leucopenia, no blood changes are present. Early diagnosis must depend on bacteriological and serological examinations. Symptomatic treatment with rest in bed is the therapy of choice. This disease, unlike *Br. melitensis* infection, often runs an acute course, septic in type, without characteristic pyrexial undulations or relapses; it terminates in recovery without notable sequels.

Chronic Epidemic Encephalitis.

375. G. P. FRETS (*Nederl. Tijdschr. v. Geneesk.*, February 1st, 1930, p. 484) records three cases, in patients aged 29, 52, and 23 respectively, in whom the diagnosis of chronic encephalitis was made before death, though the diagnosis in two of them was at first dementia praecox or psychasthenia, and in the third a toxic psychosis due to tuberculosis. In the first patient obstinate insomnia at the onset was a striking feature; in the second a long-standing suppurative otitis media was misleading. All three patients in the late stage of their disease showed symptoms of Parkinsonism. In each case the diagnosis was confirmed by post-mortem examinations. The lesions, though slight, were definite and most pronounced in the mid-brain and nasal ganglia. The pallor and atrophy of the substantia nigra was clearly seen in all, both by naked eye and microscopical examination. Here and there a slight infiltration of the vessel walls was visible. There were collections of glia cells and changes in the ganglion cells, especially in the grey substance. The second patient also showed marked changes in the cerebral cortex. In two cases there was a calcification of the vessel walls in the globus pallidus.

Enteric Fever in Children.

376. H. MOMMSEN (*Monats. f. Kinderheilk.*, November, 1929, p. 331) records his observations on 73 cases of typhoid and paratyphoid fever in children below the age of 14 years admitted to the Frankfort University Children's Clinic from 1916 to 1928. Vigorous children were more frequently attacked than weaklings. The morbidity was greater in boys (50 cases) than in girls (23 cases). Among infants and young children paratyphoid was about six times as frequent as in older children. With the exception of one case of infection by *B. suipestifer*, all the paratyphoid cases were examples of paratyphoid B infection. The enteric fever of children is characterized by a well-marked tendency to relapses, though the general condition is often little affected during their occurrence. Pronounced bradycardia was found only in severe cases at the onset, but it might last for several weeks. In relapses the pulse has a tendency to be higher than the temperature. When convalescence was well advanced tachycardia and well-marked respiratory arrhythmia were frequently observed. The mortality was 11 per cent., four deaths occurring among the boys and four among the girls.

Surgery.

Treatment of Cardiospasm.

377. THOUGH true spasm of the cardia at the junction of the oesophagus and stomach occasionally occurs, and such mechanical factors as tumours, diverticula, torsion, and stricture of the oesophagus may produce symptoms suggesting spasm, W. RIEDER (*Deut. Zeit. f. Chir.*, January, 1930, p. 47) maintains that a true hypertrophy of the muscles of the cardia analogous to the thickened pylorus seen in the pyloric spasm of infants has never been found. In most cases the delayed or defective opening of the cardia appears to be due to some muscular inco-ordination, and is frequently associated with marked dilatation of the lower part of the oesophagus. In nineteen cases under his own observation for several years Rieder has compared the effects of various methods of treatment. All the patients were treated first by conservative means—diet, lavage, psychological methods, and anti-spasmodic drugs; though three reported subjective amelioration of symptoms after the administration of atropine and papaverine, no clinical or radiological evidence of improvement was observed. All the patients were treated first by stretching with a sound or bougie; of the seven who were not subsequently treated by operation, two still suffered from vomiting when they ate quickly, two had some difficulty in swallowing in cold weather, two were almost and one entirely free from symptoms. Since *x*-ray examinations, however, showed persistent dilatation of the oesophagus with delayed emptying in each case, none could be regarded as cured. Among the other methods of treatment tried were section of the fibres of the vagus innervating the cardia and a plastic

operation. Rieder, however, found that the best subjective and anatomical results (freedom from symptoms for at least three years and rapid emptying of the oesophagus, seen on screening) followed Heller's operation, which was performed in six cases after other methods had proved unsuccessful. In this procedure a longitudinal incision 6 to 8 cm. long is made through the muscular coats of the cardia right down to, but not damaging, the mucous membrane. Three patients were cured, one patient gave a good result without complete cure, and two others were improved. It is pointed out, however, that cure of the symptoms may precede the disappearance of radiological signs by some months, especially if the oesophageal dilatation is of long duration.

378. Pneumococcal Peritonitis.

E. FRICKE (*Amer. Journ. of Surg.*, January, 1930, p. 48) comments on the rarity of this disease, and its predilection for children up to the age of 14, the incidence being greater in girls than in boys in the proportion of five to one, and occurring generally in children of the poorer classes. The onset of the disease is acute, with nausea, vomiting, severe abdominal pain, high temperature, and diarrhoea. Cyanosis of the face and lips associated with a herpes labialis is a common symptom, also tenderness over the entire abdomen with rigidity of the muscles. The pulse is better than in most cases of generalized peritonitis. A positive pneumococcus blood culture is common. The acute stage usually ends in death in a few days, but may enter a chronic stage, when the symptoms decrease in severity, but recur after about ten days with the formation of an abscess which leads to death with marked cachexia or else breaks through the abdominal wall, most frequently at the umbilicus. Out of ten cases reported, two were adults and eight children; of these eight children six gave histories of whooping-cough prior to the pneumococcal invasion. Six of the children died following operation, and the two survivors showed a tendency to chronicity from the start; one developed metastatic foci in which pneumococci were demonstrated. Both adults were women, and one who was admitted with peritonitis following abortion was treated with pneumococcus serum and survived. Contrary to the usual theory that the bacteria enter the peritoneum by way of the genital route, it is suggested that the primary portal of entry may be in the upper respiratory passages or tonsils, the fact of the disease attacking girls more frequently than boys being attributed to lessened resistance on the part of the female peritoneum to pneumococci. Expectant treatment is advocated in cases where the encapsulation and abscess formation is not complete, but an abscess must be incised and drained. It is contended that early operation in pneumococcal peritonitis is contraindicated because in its early stages it is a systemic generalized infection and operative intervention does more harm than good. Pneumococcal serum might be more widely used in early cases.

379. Primary Carcinoma of the Ureter.

O. KNEISE (*Zeit. f. Urol.*, Heft 1, 1930, p. 10), who records a personal case in a man, aged 57, who recovered after ureterectomy, illustrates the rarity of this condition by the fact that Kretschmer had been able to collect only 35 cases up to 1924, and in a certain number of these cases the tumour was not found until the necropsy. The triad of haematuria, pain, and tumour is not always present. A diagnosis, therefore, is only easy in those cases in which part of the tumour can be seen on cystoscopic examination, or when, as in Kneise's case, a bullous oedema of the mucous membrane round the ureteral opening into the bladder rouses the suspicion of a tumour. It is much more difficult to make a correct diagnosis in those cases where cystoscopy shows nothing abnormal in the bladder and ureter, but where the symptoms of haematuria or pain, or a palpable tumour, are present. The occurrence of haematuria requires investigation by all the methods of modern urological diagnosis, and Kneise condemns the use of such meaningless expressions as "essential renal haemorrhage" or "arterio-sclerotic haemorrhage." Pain is a very inconstant symptom, and only occurs when the tumour obstructs the flow of urine and so gives rise to hydronephrosis; it is therefore, generally speaking, of renal origin. Nerve pain may also occur, especially in the sciatic nerve, being caused by pressure of the tumour on the sacral plexus; the prognosis in such cases is very bad, since they are seen too late for operation to be of benefit. Neither kind of pain is characteristic of ureteral tumours, so that their presence is only of secondary importance. It is only in the rarest cases that a ureteral tumour can be palpated, and even then its real nature is not always recognized. In most cases it is only the secondary hydronephrosis or haematonephrosis that can be felt, and the presence of a ureteral tumour has to be diagnosed by other methods. The ideal treatment consists in complete nephro-ureterectomy, but in practice it may not be possible to complete it at one sitting, and ureterectomy alone may be sufficient, as in Kneise's case, where the kidney ceased to function after removal of the ureter.

Therapeutics.

380. Bismuth Therapy in Congenital Syphilis.

J. F. COPPOLINO (*Amer. Journ. Dis. Child.*, February, 1930, p. 288) reports favourably on the use of bismuth in rather large doses in the treatment of congenital syphilis in children. He uses a suspension of bismuth salicylate, camphor, and creosote in oil, 1 c.cm. of which contains 130 mg. of metallic bismuth. After starting with smaller doses, he found that no ill effects followed the use of 65 mg. for children under the age of 1 year, and twice the dose for older children. Twenty injections were given at weekly intervals, and a blood examination was made at the beginning and end of each course. If the result was positive, the treatment was continued at once, but, if negative, four weeks' rest was allowed. The maximum number of courses administered was three, after which the patients returned every month for examination and blood tests. Coppolino emphasizes the importance of asepsis, the injections being given alternately and deeply into the upper and inner quadrant of each buttock. Care must be exercised to prevent injecting into a blood vessel. After the injection the needle is left in place while the syringe is filled with air; the passage of air through the needle clears out any bismuth which has been forced back. After withdrawal of the needle, firm pressure is applied, and the part is massaged, thus reducing the likelihood of infiltration and induration. The author finds that this treatment is most efficacious in young infants, rendering them symptom-free and serologically negative; it is less useful in the treatment of older children, and does not bring about cure. The permanency of the results obtained can only be determined after the lapse of several years.

381. Therapeutic Nutrition of the Heart.

M. LOEPER and A. LEMAIRE (*Presse Méd.*, February 15th, 1930, p. 233) have studied the metabolism of patients with cardiac disease, and emphasize the importance of appropriate nutrition of the heart. They recall the fact that the metabolic rate is increased in cardiac failure, that glycogen is utilized during contraction, and that the storage of glycogen is only accomplished by the utilization of oxygen. Oxygen unsaturation in cardiac failure hinders such storage, and acidosis follows. Sodium bicarbonate should be given to counteract this, and since there is some retention of nitrogen and salts, these elements should be restricted in the diet; the fluid intake should also be limited. Chemical analysis of heart muscle has revealed that the glycogen content of the conducting tracts is less than that of the ventricular muscle, and histological studies have indicated that the former tissues distribute glycogen to the latter. Experiments on the isolated heart have demonstrated the important parts played by calcium, sodium, and potassium ions in controlling the tone of the heart. In order that sufficient salts containing these elements shall be supplied to the heart, green vegetables must be given in adequate amounts to the patient with heart disease. It has been found also that glucose exerts a stimulant effect upon the heart, and a similar action of lipoid bodies suggests that the superior effect of preparations containing digitalis leaf, as compared with those containing the alkaloid digitaline, is due to the presence of saponine in the former. The authors assume no parallelism between animals and the human subject regarding these experiments, but they adduce clinical evidence, particularly as regards the value of sugar administration to cardiac patients. They have found that the giving of 50 grams of glucose daily assists the action of digitalis, ouabain, and quinidine; in one instance fibrillation, which had been uninfluenced by quinidine, gave place to normal rhythm after several days of glucose administration.

382. Calcium Chloride and Sodium Salicylate in Pneumonia.

As in acute infective inflammations with more or less exudation the combination of calcium chloride and sodium salicylate has proved of value, H. O. NYVALL (*Clin. Med. and Surg.*, December, 1929) was led to try it in pneumonia; calcium chloride has a remote astringent effect on the process of inflammation, while sodium salicylate has an antiseptic, analgesic, and antipyretic action. In a preliminary report the results obtained in 26 cases are given, clinical details being supplied in 9. These results were considered to be more satisfactory than those following the use of vaccines

and serums. Nyvall considers that the proper and safe dose is: calcium chloride 4 grains, sodium salicylate 16 grains, and water 5 drachms; this dosage is well tolerated, and has been used in children without reaction. The solution is injected intravenously, twice daily, through the pyrexial period; once daily thereafter until the temperature and lungs are normal, and finally three times weekly, as needed. The patients are said to feel a sensation of heat while the injection is being administered, but this soon passes off. Cases of pneumonia may be aborted if treated within the first twelve to eighteen hours with calcium chloride 8 grains and sodium salicylate 16 grains. The herpes labialis and blood-stained or rusty sputum will disappear rapidly. The crisis occurs about the fourth or fifth day, and by the sixth to the ninth day the lung has returned to normal. Throughout the illness and during the stage of resolution the lungs will be freed from rales, and the temperature will remain under 102° F. No undue prostration, dyspnœa, or cyanosis occurs, and, unless an organic lesion is present, the patients recover. In very large adults and in cases in which the usual dose of 4 grains of calcium salts does not abate the threatening œdema, the dose may be increased to 8 grains.

Neurology and Psychology.

Tumours of the Corpus Callosum.

383. After describing the anatomical and physiological considerations of the corpus callosum, and the discrepancies between the physiology and the clinical evidences of its pathological lesions, R. Ironside and M. Guttmacher (*Brain*, December, 1929, p. 442) record fourteen cases of tumours of the corpus callosum, which apparently originated in and were confined to that body. A study of these emphasizes the following groups of symptoms, which define with greater clearness the clinical picture of these neoplasms. Hemiplegic weakness with pyramidal signs on the opposite side is frequent and early. Apraxia, though greatly stressed as a physical sign by other observers, was not a prominent feature of these cases, and mental changes were often the first symptom. Apathy, drowsiness, and defect of memory are more common than in growths elsewhere, and occur with such regularity in the corpus callosum syndrome as to be characteristic. Epileptiform convulsions in the series were relatively frequent, and other involuntary actions, tremor, and choreiform movement were noted throughout the cases. The occurrence of yellow cerebro-spinal fluid in four patients is considered a point of great importance, since the examination of this fluid in most cerebral tumours gives negative results. The general symptoms of cerebral tumour were mainly in abeyance, so that the diagnosis arrived at during life, in most of the present cases, was that of cerebral vascular disease. As regards other symptoms, the pupils were unequal in seven cases, and in six some degree of aphasia was present. Papilloedema was noted in nine patients, and was constantly bilateral. Headache began early and advanced equally with the psychical changes. Vomiting was much rarer; it appeared to be always accompanied by headache, and was never an isolated symptom. The authors remark that ventriculography may be of considerable diagnostic aid, as ventricular distortion is an almost constant post-mortem finding. The diagnosis of these neoplasms is largely conjectural, and their localization to particular regions of the corpus callosum is almost impossible. They must be differentiated from cerebral conditions other than tumour, and from growths in other regions of the brain. Glioma is the most common growth of the corpus callosum; thromboses along the anterior cerebral artery are very frequently met with. Short of surgical removal, treatment by radium or deep *x* rays may result in some success. Decompression is an essential preliminary to relieve the increased intracranial pressure, to allow for oedema, and to provide a window in the bone for irradiation. Their central localization renders these growths easy of access by the rays, and no severe complications need be feared from this form of treatment.

Late Pathology of Encephalitis Lethargica.

384. F. L. Reynolds and J. K. Slater (*Journ. Neurol. and Psychopath.*, January, 1930, p. 242) record the results of an investigation, based on the study of a case, which was undertaken for two reasons: first, to ascertain whether an acute attack of encephalitis lethargica from which recovery took place gave rise to organic destruction of nervous elements with consequent changes in the neighbouring neuroglia; secondly, to gain some indication whether the progressive later manifestations of disturbance of the nervous system are to be explained by a slowly progressive lesion initiated by the acute attack. The case was particularly suitable for investigation as the patient lived some eight years after a typical acute attack. The clinical symptoms from the onset are described. After the necropsy microscopical examination of the mid-brain revealed areas of great astrocytic proliferation, the cells being mostly fibrous in type. Many of the proliferated astrocytes had regressed, and formed areas of dense gliosis. Large astrocytes were found with thick processes and nuclei rich in chromatin, and some contained two nuclei; further, throughout the areas of gliosis some of the large vegetative astrocytes occurred in pairs and small groups. Thus the stages of amitotic division were present. Among the areas in which gliosis was especially pronounced were the regions of the nuclei of the third nerves, and the nuclei themselves had been encroached upon by the astrocytic proliferation. It may be assumed that acute encephalitis lethargica is due to a virus. In the present case the virus caused damage and destruction to the tissues of the mid-brain, with consequent proliferation of the interstitial (the neuroglial) cells capable of reproduction—the astrocytes. These, after proliferation, did not pass into a quiescent or passive stage. The large cells with thick processes, some with two nuclei, are typically astrocytes in an active phase of reproduction; it may be presumed that the damage is still going on and that the process has been continuous. This supposition is supported by the widespread gliosis present at the time. The histological facts can be correlated with the clinical progress of the patient. At the onset certain prominent symptoms directed attention to the mid-brain; a lesion of the central nervous system was shown by inability to converge or to look upward, and by inequality of the pupils. Consequent upon the acute attack, astrocytic proliferation and the formation of gliotic areas occurred. Shortly afterwards the patient developed involuntary movements of the legs, doubtless due to central irritation. These symptoms indicated that a disturbance of function was continuing. Typical signs of Parkinsonism then appeared, progressed, and death occurred from inanition. The continuous proliferation was due to the persistence of the virus in the tissues; during the chronic stage the effect of the virus was less intense, but, though a partial equilibrium between the toxin and tissues was established, the infective factor predominated. Both the clinical and the histological phenomena are those of a slowly progressive disease following on an acute disturbance of function, with damage and destruction of parenchymal tissue.

Congenital Syphilitic Spastic Paraplegia.

385. L. Babonneix (*La Vie Méd.*, February 25th, 1930, p. 367) describes a form of hereditary syphilitic spastic paraplegia, occurring in older children, which was first specified as a clinical entity by Marfan in 1894. Four cases are reported of this affection; the ages of the children ranged from 10 to 15 years, and in most of them the disease had existed for only about three years. In some cases the disease commences as a spastic monoplegia, which, however, is doubtless only a first phase of the paraplegia. The symptomatology is well marked. The disease occurs without known cause late in childhood (usually after the fourth year) with a slight claudication, and is slowly progressive. Clinical and radiological examinations will eliminate such conditions as Pott's disease, spina bifida, coxalgia, and Strümpell's familial spastic paraplegia. Slowly the difficulty in walking becomes accentuated, and at the end of about a year it becomes impossible. When the disease is established, typical spastic paraplegia is seen, with the characteristic gait. The feet assume the position of equino-varus, the knees touching each other; spinal tremor and exaggerated tendon reflexes appear, but there is no retraction of the Achilles tendons, and the Babinski sign is negative. Nearly always ocular and psychic troubles are noted. The eye conditions are those characteristic of hereditary or acquired syphilis—namely, the Argyll Robertson pupil, inequality of the pupils, and interstitial keratitis. The psychic disturbances consist of arrested intellectual development, inattention, feeble memory, turbulence, and tendency to fits of anger. The Wassermann reactions of both the blood and cerebro-spinal fluid are positive, and the fluid usually shows hyperalbuminosis and lymphocytosis. There is generally also a history of syphilis in the parents. Negative signs are: an absence of strict paralysis and atrophy, of sensory or sphincter troubles, and of changes in the electrical reactions; the upper limbs and face remain unaffected. The diagnosis is very easy and can be confirmed by the late onset and *x*-ray examinations. The disease progresses very slowly and lasts for years. Treatment is very limited and often of no avail. In some cases good results have been obtained with arsenobenzol, with mercury biniodide, or with specific treatment.

Obstetrics and Gynaecology.

386. Torsion of the Uterine Adnexa.

M. GUIMBELLOT (*Bull. et Mém. Soc. de Chir.*, January 18th, 1930, p. 2) describes a case of torsion of a Fallopian tube during pregnancy. A woman, aged 27, was admitted to hospital suffering from acute abdominal pain. For ten years menstruation had been abundant and accompanied by pain which necessitated rest during each menstrual period. There had been no previous pregnancy, and when seen on September 14th there had been no period since July 2nd. The acute abdominal pain, which was situated in the hypogastric region to the right of the mid-line, was accompanied by nausea, vomiting, and slight haemorrhage. On vaginal examination a soft cervix could be felt; the uterus was enlarged, with the fundus inclined to the left side. In the right fornix a very painful mass about the size of a large orange could be felt; it was separated from the uterus, and was slightly mobile. With rest the pain subsided, but the local symptoms did not alter, and the mass did not diminish in size. An exploratory laparotomy disclosed a normal uterus of about two months' pregnancy, but a mass the size of a fist and formed by the right adnexa was found in the pouch of Douglas. The tube and ovary were completely twisted; the ovary was black and about the size of a mandarin orange, while the tube was red, congested, and very oedematous. The right tube and ovary were removed and the patient made an uninterrupted recovery, followed at term by the normal birth of a healthy child.

387. Passage of Menstrual Blood through the Fallopian Tubes.

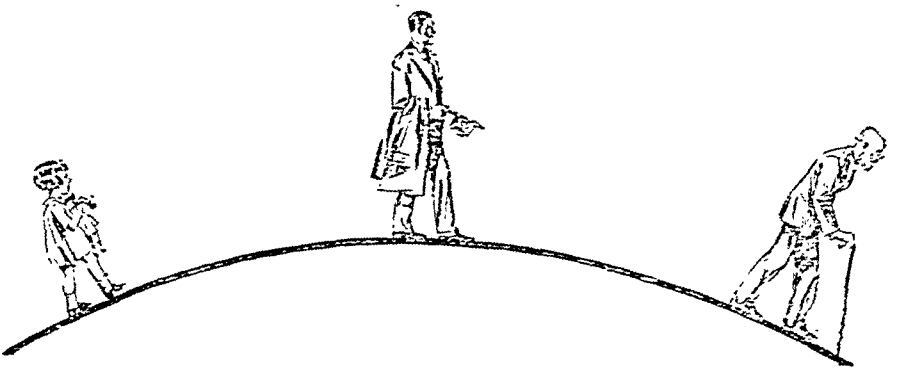
N. CANDELA (*Ann. di Ostet. e Ginecol.*, December, 1929, p. 1501) describes the case of a woman, aged 50, who had had menorrhagia for nine months, with slight metrorrhagia; the menstrual flow had diminished slightly during the last few periods. The finding of a large hard uterus with irregular surface led to a diagnosis of myoma; this was confirmed by detection of a submucous nodule within the cavum uteri during curetting. At the subsequent operation a considerable amount of free blood was found within the pelvis and abdomen, and macroscopical and microscopical examination of the specimen showed blood free within the uterus and Fallopian tubes. Extrauterine pregnancy and other sources of pelvic haemorrhage were excluded, and the inference is drawn that the haemoperitoneum was the result of the retrograde flow of menstrual blood through the Fallopian tubes. Such a flow was favoured by the presence of a large broad-based submucous myoma, of which the wide extremity was closely applied to the os internum. No endometriomatous nodule or cyst was found in the pelvis or elsewhere, but the case is recorded as illustrating the possibility of retrograde passage of endometrial fragments during menstruation. In further support of Sampson's theory of the etiology of endometrioma, allusion is made to animal experiments by Spirito in which transuterine insufflation led to passage through the tube of pieces of uterine mucosa, and the production in the peritoneal cavity of true endometriomata.

388. Vaccine Treatment of Chronic Gonorrhoea.

A. LOESER (*Zentralbl. f. Gynäk.*, January 18th, 1930, p. 163) describes the uses and limitations of his treatment of chronic gonorrhoea in the female by subcutaneous injection of living gonococci from fresh cultures. No dangerous or septicaemic sequels have been noted in a series of nearly 1,500 cases; there is a well-marked but not very painful local reaction, but the general reaction is slight and the consequent pyrexia does not exceed 0.5°C., so that if a derivative of salicylic acid is given by the mouth at the same time the injections are suitable for ambulant treatment. In acute gonorrhoea the treatment is said to be useless, except for acute arthritis. "Open" chronic gonorrhoea in the female—that of the urethra, vulvo-vaginal glands, and rectum—is not influenced by the injections, which find their application in cases of chronic gonorrhoea of the cervix (with foci of gonococci embedded deeply in the glands) and chronic gonorrhoeal adnexal inflammation. Such cases, like that of acute arthritis, are examples of "closed" gonorrhoea, and it is only this form which responds satisfactorily to the injection of fresh living gonococci. In the case of gonorrhoeal cervicitis the closure must be rendered complete during the treatment by application of an occlusive cap to the cervix for four to five days; simultaneously, repeated intracervical insertion of a pencil of some silver preparation, to kill superficially vegetating gonococci, is required. One, two, or three injections are given during two to four weeks, and cure is reported in 60 to 70 per cent. of about 170 cases, many of which had failed to respond to diverse local and general therapeutic measures. In the great majority of cases the cervical secretion becomes free from gonococci fourteen days after the first injection; at the same time the secretion becomes scantier and less rich in leucocytes. Patients who do not respond to the treatment are usually of the heavy, obese, and pasty type. The injections are prepared by making emulsions in saline solution of living virulent gonococci recently grown on ascitic agar.

Pathology.

389. The Influence of Oxidation and Reduction on the Virulence of Herpes Filtrates.



H. ZINSSER and C. V. SEASTONE (*Journ. of Immunol.*, January, 1930, p. 1) report observations suggesting that the virulence of a herpetic filtrate, which has fallen as a result of exposure to the air, may be restored by anaerobic incubation. In the first experiment the brain of a rabbit which had died of typical herpes encephalitis on the fourth day after inoculation was removed, and a quarter of it was ground up in a mortar; 100 c.cm. of Grinnell broth was added, the suspension was centrifuged, and the supernatant fluid filtered through a Berkefeld V candle. Part of the filtrate was tested immediately, and killed a rabbit in eleven days. The remainder of the filtrate was divided into two parts; one part was kept in an unsealed test-tube, the other was placed in a test-tube sealed with vaseline, after cysteine had been added in a concentration of 0.1 per cent. to assist reduction. The aerobic filtrate was tested after seventeen and twenty-four days, and proved inactive. The anaerobic filtrate tested after the same intervals killed the rabbit in five days with typical symptoms. In a second experiment a herpetic brain filtrate was divided into two portions, one being kept aerobically, the other anaerobically with cysteine. The filtrate tested immediately killed a rabbit in five days. The aerobic filtrate, when tested after eight days, was found to be avirulent; the remainder of it was therefore sealed after the addition of cysteine. This portion was tested eight, seventeen, and twenty-five days later; after eight days it was still avirulent, but after seventeen and twenty-five days it proved fully virulent. The filtrate which was sealed originally was fully virulent seventeen days after filtration. From these experiments, which the authors have been so far unable to repeat, it would appear that, under the influence of reduction, filtrates may regain their virulence after this has been lost by oxidation. The authors draw attention to Neill's experiments on the oxidation to inactivity of certain bacterial toxic agents and their subsequent reactivation by reduction, and they speculate on the possibility that the herpetic virus may be an enzyme-like cell product rather than an independently organized and living unit.

390. Transmission of Anthrax.

A. C. MARCHISOTTI and C. M. HARISPE (*Rev. Sud-Americana de endocrinol., immunol. e quimioter.*, January, 1930, p. 1), as a result of experiments on dogs and birds, came to the following conclusions. The vegetative forms of *B. anthracis* are destroyed during their passage through the alimentary canal of these animals. The spore-bearing forms, on the other hand, after being swallowed in the food, are discharged in the faeces, and their presence can readily be demonstrated by cultures. Ingestion of the flesh and viscera of animals which have recently died of experimental anthrax never gave rise to discharge of *B. anthracis* in the faeces, but cultures of the flesh and viscera of animals which had died from experimental anthrax were also negative if the flesh and viscera were exposed to a temperature of 37°C. for twenty-four hours. The process of putrefaction in this case destroyed *B. anthracis*, and sporulation did not take place. The authors conclude that carnivorous animals and birds play only an insignificant part in the transmission of anthrax among animals.

391. The Purification of Oestrin.

G. F. MARRIAN (*Biochem. Journ.*, 1929, vol. xxiii, No. 6, p. 1233) has made a quantitative study of the value of different methods of purifying oestrus-producing extracts from urine. It was found that the active principle could be obtained in the soluble fraction by treatment with 70 and 50 per cent. alcohol; it could likewise be extracted quantitatively with ether from neutral or acid aqueous solutions, but much less readily from alkaline aqueous solution. Oestrin seems to be a weakly acidic substance which can also be extracted from an ethereal solution by aqueous potassium hydroxide. Starting with 1.106 grams of unsaponifiable matter from 164 litres of urine, fractionating in turn with 70, 50, and 30 per cent. alcohol, dissolving in ether, extracting with alkali, extracting with ether from the alkaline solution after acidification, and finally extracting with alkali, the author succeeded in recovering 223,380 mouse units from an initial 309,500 units, representing about 72 per cent. of the total. The final concentrate had an activity of 1 mouse unit =0.000135 mg.

Throughout the span

of allotted years — from infancy with restricted diet, through manhood with irregularity of habits, to old age with failing muscular strength and intestinal atony, constipation besets "all types and conditions of men."

The remedy lies not in the doubtful results of harsh cathartics, but in helping the colon back to normal activity.

AGAROL
BRAND COMPOUND

The original agar-agar emulsion

is dependable, mild, non-irritating to the organs. It lubricates the intestinal tract, softens the impacted fæces, and reactivates the peristaltic force and action.

A liberal quantity of Agarol Brand Compound for trial sent without cost or obligation to physicians.

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the original Mineral Oil—Agar-Agar Emulsion with Phenolphthalein and has these advantages:
Perfect emulsification, stability, pleasant taste, without artificial flavouring, free from sugar, alkalies and alcohol, no oil leakage; no griping or pain; no nausea; not habit forming.

THE TRUTH ABOUT ULTRA-VIOLET RAY GLASS

THE GUARANTEE SEAL reproduced above appears on every sheet of HOLVIglass. It is your guarantee of permanent efficiency, backed by over 30 years' scientific reputation of Holophane Ltd.

is fully explained in the "Daylight Illumination" issue of Holophane Illumination, a free copy of which is offered to every interested reader of this paper.

In this issue the whole subject is fully discussed, and a detailed description given of HOLVIglass, the new and improved ultra-violet ray glass which is sold under a definite guarantee that it is permanently transparent to the full range of the sun's spectrum.

HOLVIglass gives the highest permanent transmission to ultra-violet rays.

BRITISH MEDICAL ASSOCIATION MEETING WINNIPEG, AUGUST, 1930.

Return by Cunard

The alternative return routes for the official Tours A1, B1 and C1 will pass through Minneapolis, Rochester (Mayo Clinic), Chicago, Philadelphia and New York.

Tours A1 and B1.

Arrive in New York Sept. 3rd.

Leave New York 11 p.m., "Mauretania," Sept. 3rd. Due Southampton Sept. 9th.

Leave New York midnight, "Tuscania," Sept. 5th. Due Plymouth Sept. 13th, or London Sept. 15th.

Leave New York 11 a.m., "Scythia," Sept. 6th. Due Galway and Cobh (Queenstown) Sept. 14th; Liverpool Sept. 15th.

Tour C1.

Arrive in New York Sept. 17th.

Leave New York by "Lancastria," Sept. 19th (midnight). Due Cobh (Queenstown) and Plymouth Sept. 27th. Due London Sept. 29th.

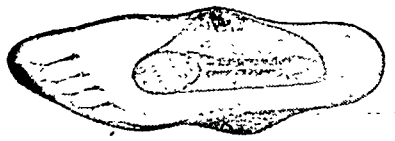
Leave New York by "Laconia," Sept. 20th, 11 a.m. (via Boston). Due Belfast Sept. 28th. Due Liverpool Sept. 29th.

Approximate cost of Tours:
Tour A1—£109/17/6. Tour B1—£121/19/2 (if travelling Saloon "Mauretania" approximate additional cost £30). Tour C1—£170/5/-.

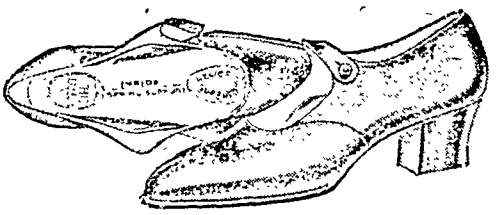
Further information and full details of the Tours may b obtained from the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, London, W.C.1.

CONVINCING

Here is an extract from a recent report by a Public Health Authority—



. . . . . Gratifying results were also obtained in cases of corneal ulcers and of rheumatism. The experience of six months' use of the lamps indicates that ultra-violet radiation is a very valuable addition to our methods of treatment. Both types of lamps gave good results, but cases appeared to show signs of improvement more quickly with the mercury vapour lamp than with the carbon arc . . . . . .



Hanovia are the Pioneers. 163,000 lamps are in use. Free service after purchase.

METATARSALGIA

FOOT TROUBLES RELIEVED

NOTE the way in which the foot rests in position supported at both sides and underneath.

M. 191.
Korcet Soft Tread One Bar Shoe.
35s. 9d.

MEDICAL MEN can rely upon their patients obtaining immunity from foot pains when correctly fitted with these shoes, which have been warmly approved by eminent surgeons. The construction includes, among other features, straight inside line, insoles extended laterally so as to fit up round the waist of the foot, and underneath the arch a firm but resilient spring, also a metatarsal cushion. Korcet Sort Tread Shoes give prompt relief in cases of metatarsalgia and wherever there is any tendency to flat-footedness. *Booklet on application.*

KORCET SOFT TREAD SHOES

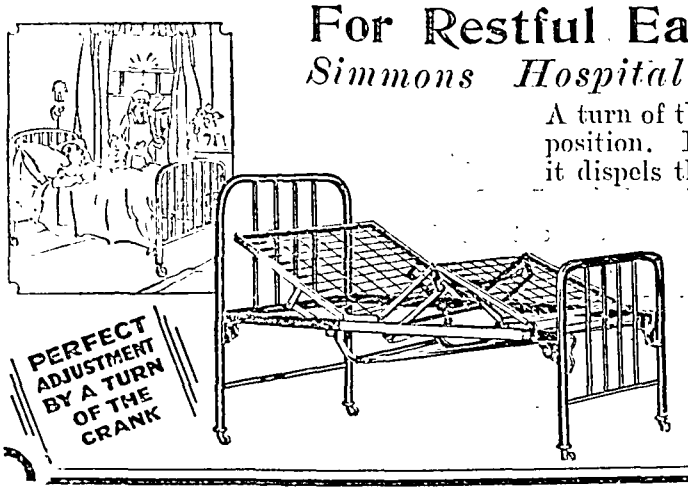
KORCET SHOE CO., LTD., HENRY STREET, NORTHAMPTON.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.



MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

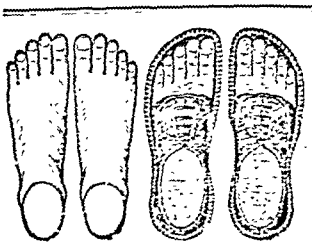
The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD



Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

CLOTHES for DOCTORS

TERMS:
£1 PER MONTH
NO REFERENCES
OR ENQUIRIES

THE old-fashioned method of buying clothes, with its heavy interest charges, is fast becoming obsolete.

Its place is being taken by the new Keith Bradbury system, which is more convenient to customers and certainly more profitable to the tailor.

As so few men make special financial provision for their tailoring needs, delayed payment of accounts for six or twelve months, or perhaps longer, does not help the customer—yet it involves the tailor in considerable interest charges which must eventually be passed on to the customer in the form of overhead expenses.

On the other hand, small periodical payments are hardly missed from one's income, and as a result, the question of clothing becomes a pleasure instead of a bore, apart from which, it enables the tailor to avoid heavy interest dues, which must mean better value for the customer.

Concrete proof of the financial merit of this new system of periodical payments (without references or enquiries) is to be found in the fact that Keith Bradbury Ltd. are able to provide a FREE VALET SERVICE for the care of customers' clothes after purchase, in addition to supplying West End clothing at the low prices quoted in this announcement.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

EXPERT VALUES HILLMAN AT OVER TWICE ITS PRICE

"Everything I have said I would say again if the car cost £1,000, but as a matter of fact it costs less than £500."

That is what Mr. A. Percy Bradley, Clerk of the Course at Brooklands and expert Motoring Critic, writes in an article on the Hillman Straight Eight in the 'Sphere.'

Here are some of the points he mentions:

"Improved almost out of recognition in a very short space of time . . . speeds in excess of 60 m.p.h. and at no point in its range is there the slightest trace of vibration . . . I know of no other car that goes along more smoothly or more silently. . . . The suspension is beyond criticism and the steering is in the same category. . . . I can make no suggestion as to how any part of it could be improved."

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. *The food should be easily digestible, nourishing, and given a little at frequent intervals*
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

DIABETES

Brusson Bread, which has the lowest starch content of any starch-reduced gluten bread, provides a *scientific aid in adjusting the carbohydrate to the* patient's tolerance. Its scientifically graded content of starch, protein, and fat enables the physician to prescribe the correct quantity for each patient.

Liberal samples free to Medical Men on request. Also a copy of "The Amplified Diet in Diabetes," often very useful for giving to patients.

Apply to Superintendent.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach

Resident Physicians: BERTHA M MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.
Tel.: 64117. *For terms etc., apply to the Medical Superintendent.*

TAKE A NOVEL HOLIDAY AND SEE WONDERFUL CANADA!

Banff - Famous Beauty Spot

BANFF, in the Canadian Rockies, is one of the most famous mountain resorts of the world, to which flock the cosmopolitan crowds of several continents.
And what a view as you look down the Bow Valley! Snow-crowned peaks, rivers, dense green forests, a superb golf course, and Banff Springs Hotel (looking like a Scotch castle) in the centre of that beautiful picture.
There's enough to do at Banff to keep you the whole summer—scenery, trail riding to Mount Assiniboine or Mystic Lake, mountain-climbing, hiking, riding, golf, tennis, dancing. At the hotel there is swimming in warm sulphur baths—for Banff has several springs. There are cowboys, trappers, Indians, quaint western characters. The annual Indian "Pow Wow" and Highland Gathering are very notable events.
Smooth motor roads invite you to other Rocky Mountain centres—lovely Lake Louise, the Yoho Valley, the Kicking Horse Trail, Kootenay National Park, Lake Windermere.
Banff is one of the 35 places on our "Across Canada" Tour—a seven-week trip through the Rockies to the Pacific Coast and back. Some of the other places are Quebec, Montreal, Ottawa, Toronto, Niagara, Winnipeg, Lake Louise, Calgary, Vancouver, Victoria, Windermere Valley, and Nipigon.
The Tour starts July 25th, sailing by the DUCHESS OF YORK. Special train detailed to party, kept waiting while you are sight-seeing. "All-in" price includes steamship, railway, and sleeping car fares, hotels, meals, drives, transfers, guide and gratuities.
And then from June 27th to August 15th we have 11 shorter tours, from 19 to 26 days, visiting some of the principal sights of Eastern Canada—some of them including New York.
Or "Go-as-you-please" holidays? We will gladly prepare itineraries, short or long.

We have just issued a beautiful little book with 32 colored illustrations on Holidays in Canada. Shall we send you a copy of it? Ask for Booklet about Tour C.12.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel.: Welbeck 8901.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (*Primary & Final.*) CH.M.EDINBURGH.
F.R.C.S.EDINBURGH. M.C.CANTAB.
M.S.LONDON.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"*How to Pass the F.R.C.S.*," *free on application to the Secretary.*

County Borough of Huddersfield.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH, CHIEF SCHOOL MEDICAL OFFICER, ADMINISTRATIVE TUBERCULOSIS OFFICER, MEDICAL OFFICER UNDER MENTAL DEFICIENCY ACTS, and HOSPITALS SUPT.

The Huddersfield Corporation invite applications from fully qualified and registered Medical Practitioners, who are also holders of a diploma in Sanitary Science, Public Health, or State Medicine for the position of Medical Officer of Health for the County Borough, with which is combined the other offices above mentioned.

The gentleman appointed will be responsible for the performance of all duties now devolving upon the Medical Officer of Health and School Medical Officer, or which may be in future assigned to him.

Candidates must not be more than 45 years of age, and the salary will be £1,100 per annum.

The successful applicant will be required to reside in the Borough, to devote his whole-time to the duties of the office, and not to engage in private practice.

The appointment is to be held in accordance with the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926, and is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, the successful candidate being required to pass a medical examination and to pay contributions at the rate of 5 per cent. to the Superannuation Fund.

Applications, stating age, qualifications, and experience, accompanied by eight copies thereof and by eight copies of three recent testimonials, and endorsed "Medical Officer of Health," must reach me not later than Saturday, May 3rd.

Applications should also give three references other than the signatories to the testimonials.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Town Hall, Huddersfield. J. HENRY FIELD, Town Clerk.
April 5th, 1930.

Borough of Wednesbury.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Town Council invite applications for the appointment of Medical Officer of Health, School Medical Officer, Maternity and Child Welfare Officer, and Superintendent of the Corporation's Hostel for Ailing Babies, for the Borough of Wednesbury.

Salary £800 per annum, rising by biennial increments of £50 to £900 per annum.

Applicants, being fully qualified and duly qualified registered Medical Practitioners, must have such additional qualifications as are prescribed in the Sanitary Officers Order, 1926.

The appointment will be made in accordance with the provisions of the Public Health (Officers) Act, 1921, the Sanitary Officers Order, 1926, and the orders and directions of the Council, and will be subject to the approval of the Minister of Health and the Board of Education.

The officer appointed will be required to devote his whole time to the duties of the position, and to reside within the Borough.

Applications, accompanied by copies of not more than three recent testimonials, must be sent to the undersigned on or before May 5th, endorsed "Medical Officer of Health."

Town Hall, Wednesbury. N. P. LESTER, Town Clerk.
April 12th, 1930.

City of Birmingham.

MATERNITY AND CHILD WELFARE DEPT.

Three TEMPORARY MEDICAL OFFICERS are required from July 1st to October 8th. Applications are invited from ladies who have had Obstetrical experience and an appointment in a Children's Hospital. The salary offered is ten guineas per week.

The appointment cannot be terminated within the period named.

Applicants should be sent to the Medical Officer of Health, Council House, Birmingham, on or before May 17th.

City of Birmingham.

MATERNITY AND CHILD WELFARE DEPT.

RESIDENT MEDICAL OFFICER.

A Resident Medical Officer is required on July 1st next, for a period of six months, for the City Babies' Hospital (50 beds). Salary at the rate of £150 per annum, with board and laundry. Previous experience in a Children's Hospital desirable. Apply, giving all particulars of qualifications, age, and references, to the Medical Officer of Health, Council House, Birmingham, on or before May 17th.

Worcestershire County Council.

ASSISTANT COUNTY MEDICAL OFFICER (Male).

The above-mentioned Council are about to appoint an Assistant County Medical Officer, and applications are now invited for this post.

Applicants must be registered Medical Practitioners between the ages of 25 and 45 years. Special experience and qualifications in Tuberculosis will be necessary as work under the County Tuberculosis Scheme will form the chief part of the officer's duties. He should have (1) at least three years' experience in the practice of his profession; (2) spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases; and (3) received special training, for a period of not less than six months, in the diagnosis and treatment of tuberculosis. A Diploma in Public Health is desirable. The officer who is appointed will work under the supervision of the Chief Tuberculosis Officer.

The person appointed will be required to reside in the district assigned to him by the County Council and to devote the whole of his time to the work.

The salary will be £600 per annum, with an allowance of £140 per annum for use of his own motor car. The engagement to be subject to three months' notice on either side. The post is designated under the Local Government and Other Officers Superannuation Act, 1922.

Applications (on forms to be obtained from the County Medical Officer, 29, Foregate St., Worcester), accompanied by not more than three recent testimonials, must be received by 12 noon on April 30th, addressed to the County Medical Officer, 29, Foregate St., Worcester.

Canvassing disqualifies, and neither the names of the members of the County Council nor of the Committee will be supplied.

Shirehall, Worcester. (Sgd.) C. H. BIRD, Clerk of the County Council.
April 8th, 1930. (W.99.)

Lancashire County Council.

PUBLIC ASSISTANCE COMMITTEE.

PARK HOSPITAL, DAVYHULME, near MANCHESTER.

APPOINTMENT OF JUNIOR RESIDENT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (men) for the appointment of a Junior Resident Medical Officer at the above Hospital. Candidates should be unmarried. The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period. The salary is at the rate of £200 per annum, together with the usual residential allowances.

The Hospital comprises 500 beds.

Applications, accompanied by copies of not more than three testimonials, should be addressed to the County Medical Officer, Public Assistance (Hospital and Medical) Department, County Offices, Preston, not later than May 17th.

County Offices, Preston. GEORGE ETHERTON, Clerk of the County Council.
April, 1930.

City of Salford.

April 17th, 1930. Gen. Supt. & Sec.

Royal West Sussex Hospital,
CHICHESTER. (111 Beds.)

The Board of Management invite application for the post of JUNIOR HOUSE SURGEON, male. Salary £150 per annum, with board, residence, and laundry.

Applications, stating age, with three recent testimonials, should reach me not later than May 2nd.

Particulars as to duties will be forwarded to candidates on receipt of their application.

HERBERT S. AYLMORE, Secretary.

Metropolitan Borough of HAMMERSMITH.

TUBERCULOSIS OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Tuberculosis Officer and Assistant Medical Officer of Health for the borough of Hammersmith.

The salary attaching to the appointment is £450 per annum, rising by annual increments of £50 to a maximum of £1,000, but in fixing the commencing salary regard will be had to the qualifications and experience of the gentleman appointed.

Candidates must be qualified to hold an appointment as Tuberculosis Officer in accordance with the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, and must also possess the Diploma of Public Health.

The gentleman appointed will be required to devote his whole time to the duties of the office. The chief duties will be in connection with tuberculosis, but the successful applicant will also be required to assist in the general work of the Public Health Department under the supervision of the Medical Officer of Health.

The appointment will be subject to the provisions of the Council's Superannuation Scheme, and the successful applicant will be required to pass a medical examination.

Applications on forms to be obtained from the undersigned, accompanied by copies of not more than three recent testimonials, must be delivered at the Town Hall, Hammersmith, W.6, in envelopes, endorsed "Tuberculosis Officer," not later than May 12th.

Canvassing will be a disqualification.

HUGH ROYLE, Town Clerk.

City and County of Bristol.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council invite applications for a whole-time Assistant Medical Officer of Health. Age not exceeding 40 years. Salary £500 per annum. The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The duties will consist principally of examination of children in the Council's Secondary, Elementary, and Special Schools, treatment in School Clinics, etc., but the officer appointed will also be required to work in all departments of the Medical Officer of Health of the City and Port.

Applications, which must be on a form provided for this purpose, should be accompanied by not more than three recent testimonials, and must be received by the undersigned not later than Monday, May 5th. Envelopes should be endorsed "Assistant Medical Officer of Health."

Canvassing will disqualify.

JOSIAH GREEN, Town Clerk.

Council House, Bristol.

April 12th, 1930.

Hospital of St. Cross, Rugby.

(114 Beds.)

Applications are invited for the posts of SENIOR and JUNIOR RESIDENT MEDICAL OFFICERS (males).

Candidates must be registered Medical Practitioners, and must be prepared to begin duties on May 1st. Salary for the Senior post at the rate of £150 per year. Junior at the rate of £100 per year, with board and residence in the Hospital.

Candidates are requested to state whether they are prepared to accept the post of Junior if not selected for the Senior office.

The appointments are for a period of six months only, at the end of that time the Junior will be eligible to apply for the Senior post, which then becomes vacant.

The Hospital is recognized by the University of London for the purpose of the M.D. and M.S.

Applications, stating age and qualifications, with copies of three recent testimonials, should be sent to me immediately.

April 17th, 1930.

Merthyr General Hospital, MERTHYR TYDFIL.

Applications are invited for the post of RESIDENT HOUSE SURGEON at the above Hospital (male) for a period of six months. Salary at the rate of £150 per annum, with board, rooms, and laundry.

Applicants must have had experience in administration of anæsthetics. Duties to commence in May.

Applications, stating age and qualifications, and enclosing copies (only) of not more than three testimonials, should be addressed to the Secretary, Hon. Medical Staff, Merthyr General Hospital.

Applications are invited for the

post of RESIDENT MEDICAL OFFICER (male) at the DUMFRIES & GALLOWAY ROYAL INFIRMARY. The Institution, which contains about 120 beds, is one of the Premier Provincial Hospitals in Scotland, and offers an especially good opportunities of training. Experience in all branches of the profession. Salary at the rate of £100 per annum for the first six months and £150 per annum for the second six months.

Applications, with testimonials, to be forwarded to the Treasurer, Dumfries & Galloway Royal Infirmary, 84, Irish Street, Dumfries, not later than

The Royal Infirmary, SUNDERLAND. (290 Beds.)

Wanted June 1st, HOUSE PHYSICIAN (male). Salary £140 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, and accompanied by copies of testimonials, to be sent to the undersigned.

S. C. FRYERS, House Governor & Secretary.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of *HONORARY SURGEON*, for which a present Honorary Assistant Surgeon is a candidate. In the event of his election, there will be a vacancy for an HONORARY ASSISTANT SURGEON, for which applications are also invited.

Candidates must be Fellows of one of the Royal Colleges of Surgeons of England, Edinburgh, *or* Ireland. The successful candidate will be required, in addition to other duties, periodically to deliver surgical courses of Lectures to the Nurses, and to undertake such teaching for the Post-Graduate College as the Board may approve.

Applications, with copies only of testimonials, must reach me not later than Thursday, May 22nd. Candidates must attend the meeting of the Medical Council on Friday, May 23rd, at 4.30 p.m., and prior to that date call upon and *send copies of application and testimonials to each member thereof*. They must not canvass members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and, if so notified, attend a meeting of the Board at 5 *p.m. on Tuesday*, May 27th, when the election will be made.

H. A. MADGE, Secretary.

Leicester Royal Infirmary.

HONORARY SURGEON.

A vacancy will occur on June 1st for an Honorary Surgeon, consequent upon the retirement, under the Rules, of Mr. Cecil Marriott, M.Ch., F.R.C.S., Senior Honorary Surgeon. Applications are invited for the post. Past and present members of the Assistant Honorary Staff are primarily eligible for election to full Staff appointments. The Senior Honorary Assistant Surgeon, Mr. R. S. Lawson, F.R.C.S., *is an applicant*.

HONORARY ASSISTANT SURGEON.

Under the above announcement, a vacancy is expected for an Honorary Assistant Surgeon. Candidates should be Fellows by examination of the Royal College of Surgeons of England, or Graduates in Surgery of one of the Universities of the United Kingdom of Ireland. A *grant of fifty guineas* annually is made for out-of-pocket expenses. Applications (*accompanied by 100 copies of testimonials*) to reach the undersigned by Monday, May 12th. The appointment will be made on May 14th.

Canvassing for appointments is *not* allowed.

HARRY JOHNSON,
April 14th, 1930. *House Gov. & Sec.*

London Jewish Hospital,
Stepney Green, E.1.

Excellent house in own grounds, with good garden and tennis court, containing 3 reception, 5 bedrooms, etc. Garage. Electric light. Price £1,750. Sport of all kinds, and good schools near. Premium £2,000.
5. HANTS.—COUNTRY PRACTICE.—Very old-established, situated in most attractive district near Sussex Border. Receipts average over £800 p.a. Panel of 480. Detached house in half an acre of garden, 2 reception, 5 bedrooms, etc. Rent £55 p.a. Hunting, golf, etc., and first class schools within reach. Premium £1,300.
6. LONDON, EAST.—PARTNERSHIP.—A one-half share is for disposal in an old-established chiefly working-class and panel Practice, averaging about £2,800 p.a. Panel of 3,600. Visits 2/6 to 5/6. Very suitable small house, with 3 bedrooms, bathroom, etc. Garden. Rent on lease £50 p.a. Premium £2,500.
7. LADY DOCTOR'S PRACTICE.—KENT.—Within 40 miles of London. In a town of 100,000 a well-established middle and working-class Practice, worth last year £850, including panel of 200. Visits 3/6 upwards. Mids. from 3 gns. (20 cases yearly). House, with good accommodation. Rent on lease (15 years to run) £65 p.a. Premium £1,200. Practice equally suitable for Medical Man.
8. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
9. DUNDEE.—Well-established PRACTICE in good residential area, offering large scope particularly for panel and midwifery. Income last year over £750 and increasing. Very well situated house, with ample accom. Price £2,800 or can be rented. Prem. £750 or near offer.
10. YORKS.—In a clean and thriving manufacturing town, an old-established Homœopathic and partly Allopathic PRACTICE, held about 50 years by Vendor who is retiring. Cash receipts for the past three years average £2,400 p.a. Patients middle and better-class. Midwifery refused. Good house available, rent £100 p.a. Premium only one year's purchase, part down and balance by arrangement.
11. SURREY.—Attractive residential district within 20 miles.—Mixed-class PRACTICE producing about £700 p.a., but capable of much increase, as neighbourhood is developing. Panel of 500. Fees 2/6 upwards. Very nice house, with 3 reception, 8 bedrooms, and three acres of garden. Rent on lease £165 p.a. Smaller house available if desired. Premium £1,200.
12. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
13. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—Old-established mixed general PRACTICE. Average income nearly £1,900. Panel of 2,500. Fees 2/6 to 7/-. No mids. No Assistant kept. Well-situated house, with good accommodation. Rent on lease £120. Prem. £3,300.
14. WITHIN 40 MILES OF LONDON.—In a thriving Riverside and Hospital town (pop. over 40,000).—Old-established mixed-class and increasing PRACTICE worth over £2,300 last year, including panel of 1,600 to 1,700. House contains professional accommodation, 2 reception 4 bedrooms, bathroom, etc. Small garden and garage. Rent on lease £60 p.a. Premium £3,650, to include good book debts of £500, drugs, etc., and consulting room and surgery furniture.
15. BORDERS OF BERKS AND HANTS.—In a delightful district, an old-established mixed-class PRACTICE averaging for the past three years £[illegible] p.a. (last year £973), including panel of 400. Visits 5/- to 12/6, medicine extra (3/6). Very little midwifery. One opponent. House contains ample accommodation (2 sitting rooms, 7 bedrooms, 1 bathroom, etc.) Large garden and garage. Water laid on and gas part installed. Rent £50 p.a. Premium £1,400. Excellent sport.
16. PARTNERSHIP.—WEST MIDLANDS.—The Third share (with increase to half in 4 years and eventual succession if desired) is offered in very old-established mixed-class Practice in small town, largely residential, in midst of agricultural district of exceptional beauty. Cash receipts average £2,357 p.a., including panel of 1,084. Opposition not strong. Expenses light. Choice of two houses (small) which can be bought for £600 or £700. Premium 2 years' purchase.
17. SURREY.—In a beautiful residential district within 40 miles of London (good train service) a small mixed-class PRACTICE worth about £600 p.a. and offering scope. Select panel of 200. Charming house with ample accommodation in very pretty grounds (tennis court, etc.) of 1¼ acres. Price, freehold, £3,500. Premium 1½ years' purchase.
18. SOUTH-WEST OF ENGLAND.—Old-established and increasing PRACTICE in pretty district 5 miles from Hospital town and within 10 miles of the sea. Income last year £1,489, including Union, etc. (£105) and panel of 780. Railway station near. Detached house (professional rooms, 2 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Rent on lease £45 p.a. Premium £2,100.
19. WITHIN FIFTY MILES OF LONDON.—In a pretty residential district, a well-established PRACTICE averaging over £700 p.a., including panel of 538, and appts. worth about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Elec. light. Price for freehold £3,000. Premium £1,050. Exceptionally good educational facilities for boys.
20. LARGE UNIVERSITY CITY (WEST).—Good-class old-established non-dispensing PRACTICE worth last year £1,274, including select panel of about 350. Visits up to 21/-. Very little midwifery. Good house in best part of City, overlooking park, with ample accommodation. Vendor's freehold, but will be let on lease. Premium only £1,200.
21. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, experienced, 30 to 35 years of age and married preferred) can acquire a share (producing at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house, with ample accommodation, garden, etc., on rental. Premium 2 years' purchase. Short preliminary assistantship essential.
22. SOUTH-WEST OF ENGLAND.—GOOD HOSPITAL TOWN.—A one-half share in an old-established mixed-class PRACTICE is offered owing to the retirement of the Junior Partner. Gross cash receipts average £2,300 p.a., including good appts. Small panel. Low expenses. Commodious house, with garden and garage, rent £70 p.a. Premium 2 years' purchase. Vendor on staff of Hospital, and scope for surgery.
23. YORKS.—LARGE TOWN.—Very old-established middle and working-class PRACTICE, offering exceptional scope for increase. Income for last year £1,500, including panel of over 1,700. Visits 4/6 to 5/-. Conveniently situated house, with 2 reception, 4 bedrooms, etc. Rent on lease £56 p.a. Premium £2,250.
24. SOUTH DEVON.—PARTNERSHIP.—Attractive Town close to sea.—A half share in very old-established and rapidly increasing mixed general Practice. Average cash receipts last 3 years £2,727, last year £3,521. Panel of 1,130. Fees 3/6 to 21/-. Good house in its own grounds with ample accommodation. Price freehold £1,900, £1,200 on mortgage. Prem. £2,300. Cottage Hosp. and good scope for major surg.
25. PARTNERSHIP.—OXON.—Delightful residential district, near good town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,540, and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 1 year's purchase.
26. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 380. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1 year's purchase.
27. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
28. SOUTH-WEST OF ENGLAND.—POPULAR COAST TOWN.—A one-third share in an old-established PRACTICE, having good surgical scope. Gross cash receipts average £4,200. Panel of 1,800. Suitable house available, on rental. Premium £2,250.
29. CAMBS.—Old-established Country PRACTICE, near good town, averaging for the past three years over £1,200 p.a. Panel of 870. Visits 5/- upwards, medicine extra. About 30 cases of midwifery from 2 to 3 gns. Nice house, with 2 reception, 6 bedrooms, etc., and garden. Rent on lease £80 p.a. Premium £1,800.
30. NOTTINGHAM.—Old-established good middle and working-class PRACTICE. Income from panel nearly £700 and large scope for general practice. Good well-situated house. Rent on lease £80. Premium £1,200, payable £600 cash and balance by instalments.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-
SANDOZ CHEMICAL WORKS PHARMACEUTICAL DEPT.
5, WIGMORE STREET, LONDON, W. 1.

A Striking Contribution to Gynaecological Organotherapy

Original Packings:
Bottles of 10 dragées (250 M.U.) 16 6 per bottle.

Boxes of 6 x 1 c.c. ampoules (100 M.U.) 12 - per box.

Owing to a reduction in manufacturing costs due to new and improved methods of preparation, it has now been possible to reduce the price of "Progynon" dragées. The nature of the raw material employed, high degree of concentration, system of constant biological control, etc., remain, however, unchanged.

Trade Mark **'PROGYNON'** Brand

Female "cyclical" hormone

of high concentration and activity.
Biologically standardised according to the method Allen and Doisy.

Direct Causal Effect by ORAL ADMINISTRATION

IN THE TREATMENT OF MENSTRUAL AND MENOPAUSAL DISORDERS DUE TO OVARIAN HYPOFUNCTION.

Also available in the form of ampoules for intramuscular injection.

With 273 Illustrations. Crown 8vo. 12s. 6d. net; postage 6d.

MINOR SURGERY

By LIONEL R. FIFIELD, F.R.C.S.Eng., late Surgical First Assistant and Registrar, London Hospital; Demonstrator of Anatomy and late Demonstrator of Minor Surgery, London Hospital.

"... *absolutely up to date ... can be confidently recommended in* the teaching, study, and practice of minor surgery."

—BRITISH JOURNAL OF SURGERY.

BY THE SAME AUTHOR.

With 67 Illustrations (2 in colours). Crown 8vo. 9s. net; postage 5d.

INFECTIONS OF THE HAND

"... an important *contribution to a subject of unquestionable im*portance ... excels on the clinical side."—BRITISH MEDICAL JOURNAL.

With 130 Illustrations. Demy 8vo. 12s. net; postage 9d.

A SHORTER ANATOMY, with Practical Applications

By E. WOLFF, M.B., B.S.Lond., F.R.C.S.Eng., Demonstrator of Anatomy, University College, London; Chief Clinical Assistant, Moorfields Ophthalmic Hospital.

"... an eminently readable little book ... gives accurate information *in a simple* and lucid way. The illustrations are clear."

—THE LANCET.

With Illustrations. Demy 8vo. 12s. 6d. net; postage 9d.

ELEMENTARY MEDICINE in Terms of Physiology

An Introduction to Clinical Work.

By D. W. CARMALT JONES, M.A., M.D.Oxon., F.R.C.P.Lond., Professor of Systematic Medicine, University of Otago, New Zealand; Physician, Dunedin Hospital, New Zealand; Consulting Physician, Westminster *Hospital, etc.*

"Excellent in every respect and very readable."—GUY'S HOSP. GAZ.

IN THREE VOLUMES. Medium 8vo. With 1,072 Illustrations. £5 6s. net.

KAUFMANN'S PATHOLOGY

Authorised Translation of the "Lehrbuch der Pathologischen Anatomie."

By Dr. EDUARD KAUFMANN, Professor of General Pathology and Pathological Anatomy and Director of the Pathological Department, University of Göttingen, etc. Translated by STANLEY P. REIMANN, M.D., Pathologist and Director of the Research Institute of the Lankenau Hospital, Philadelphia, etc.

"One of the best known and most widely valued works ... The *book has obtained a world-wide reputation.*"—BRITISH MEDICAL JOURNAL.

"... has long been recognized as the leading work in this subject ... it should be in every pathological laboratory and library."

THE LANCET.

SIXTH Edition. Plates from Original Drawings (6 in Colours) and other Illus. in Text. Demy 8vo. 30s. net; post. 9d.

ON DISEASES OF THE LUNGS AND PLEURÆ

Including TUBERCULOSIS AND MEDIASTINAL GROWTHS.

By Sir RICHARD DOUGLAS POWELL, Bt., K.C.V.O., M.D.Lond., F.R.C.P., late Physician-in-Ordinary to H.M. the King; Consulting Physician to the Middlesex and Brompton Hospitals; and Sir PERCIVAL H.-S. HARTLEY, C.V.O., M.D.Camb., F.R.C.P., Physician, St. Bartholomew's Hospital; Senior Physician, Brompton Consumption *Hospital, etc.*

"... can be confidently recommended as a safe guide to the practitioner in search of authoritative medical opinion in this country at the present time."—BRITISH MEDICAL JOURNAL.

SEVENTH EDITION. With New Illustrations (mostly in Colour). Demy 8vo. 7s. 6d. net; postage 5d.

LANDMARKS AND SURFACE-MARKINGS OF THE HUMAN BODY

By L. BATHE RAWLING, M.B., B.C.Cantab., F.R.C.S.Eng., Surgeon to St. Bartholomew's Hospital, etc.

"This edition will doubtless be as popular as its predecessors, both with students and surgeons."—BRITISH MEDICAL JOURNAL.

SECOND Edition. Ninth Impression. Post 8vo. 7s. 6d. net; postage 6d.

AEQUANIMITAS:

With other Addresses to Medical Students, Nurses, and Practitioners of Medicine.

By Sir WILLIAM OSLER, Bart., M.D., F.R.S., late Regius Professor of Medicine, University of Oxford, etc.

"Written with all the breadth of view and the beauty of style which make Professor Osler's writings so characteristic and so valuable."

THE LANCET.

THIRD Edition. Leather. 12s. net; postage 5d.

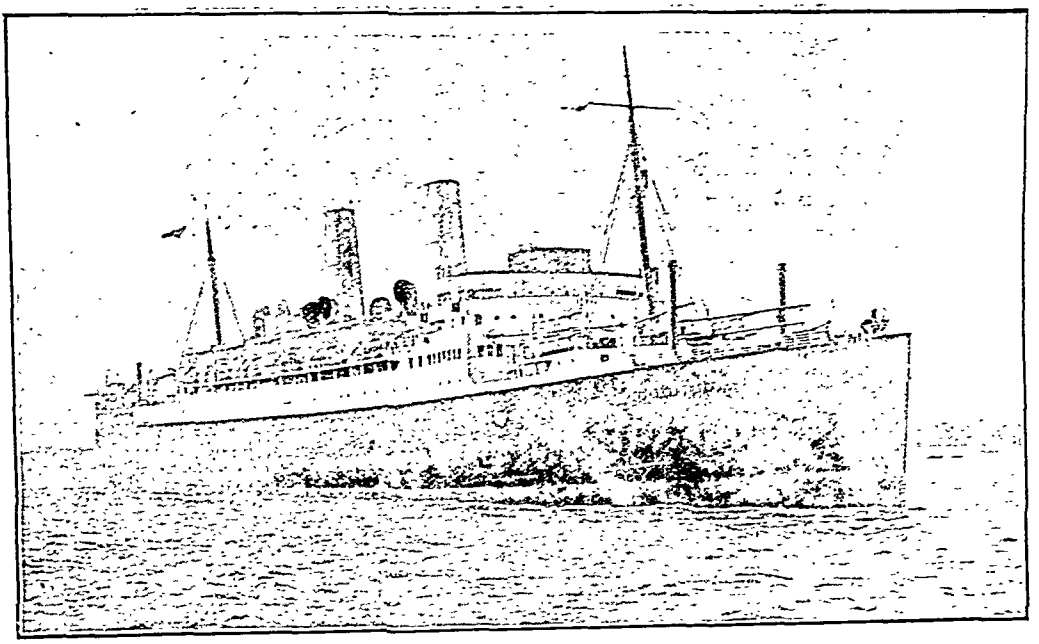
Immediate action is necessary

The 98th ANNUAL MEETING

is this year to be held in the Dominion of Canada.
WINNIPEG is the centre which has been selected.

The British Medical Association and the Canadian Medical Association, in collaboration with the Canadian Pacific Railway and Steamships, have arranged a number of attractive journeys for B.M.A. Officers and Members taking part in the Meeting.

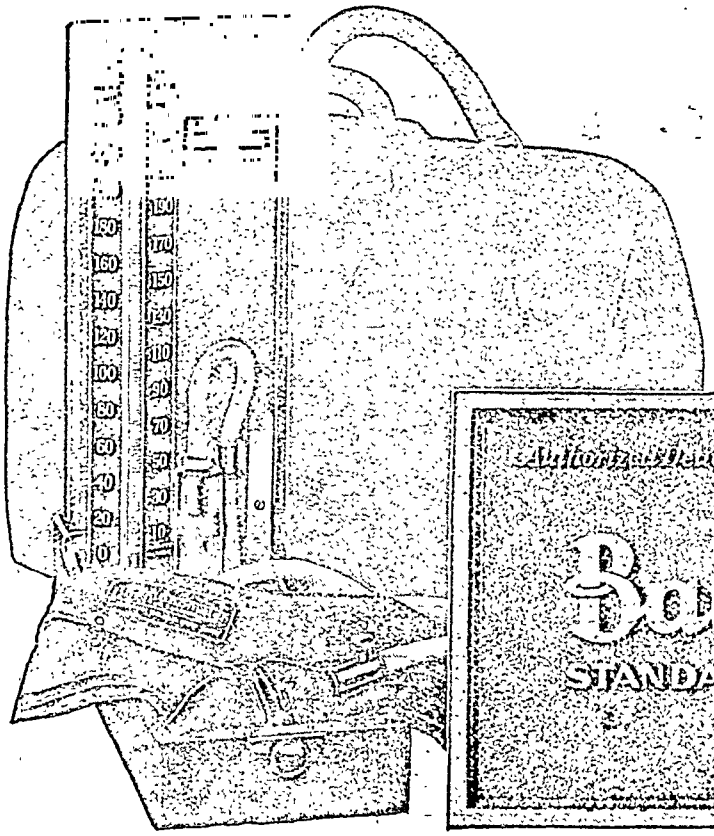


These Official Tours will leave England on AUGUST 8th and AUGUST 15th by

CANADIAN PACIFIC DUCHESS STEAMSHIPS

"DUCHESS OF BEDFORD" - AUGUST 8th.
"DUCHESS OF YORK" - - AUGUST 15th.

Make up your mind to attend this Meeting, which is taking place

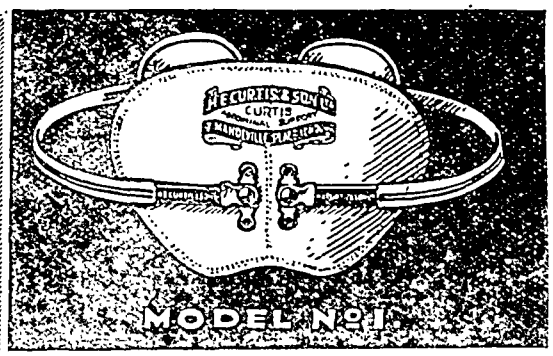


AUGUST 26th to 29th, 1930

A CANADIAN PACIFIC LINER. 20,000 TONS

All information can be obtained, and Registrations must be made, through the Financial Secretary of the Association at

BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, W.C.1.



ON YOUR DESK—OR IN YOUR BAG— THE LIFETIME GUARANTEE ON THIS SUPREME INSTRUMENT ASSURES YOU OF PERFECT, UNINTERRUPTED, BLOOD PRESSURE SERVICE FOR YOUR LIFETIME!

THE ONLY SUPPORT

Giving direct abdominal uplift

Maintained in any position that the patient may assume without any cramping or binding of the hips whatsoever. The principle is that of a direct anterior-posterior pressure, and enjoys numerous advantages over any other make of support on the market. It is simply fastened by a strap and buckle, and can be adjusted to any degree that the physician may prescribe.

Disturbances of Menstruation & the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases. The chemical composition of Kalzana, calcium-sodium-lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

Kalzana is dispensed by Chemists in air-tight packets containing 50 and 100 tablets. Free from harmful by-effects and is pleasantly flavoured.

Kalzana

Made by A. WULFING & CO. (Foreign Produce).

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available at 15/- per 1,000 tablets. Adequate samples for clinical trials, sent with pleasure, upon request.

OVALTINE

MALNUTRITION IN CHILDREN

Nervous and mentally unstable children are numerous, and their condition, being naturally deep rooted and inherent in the organism (as neuroses and psychoses are not of sudden onset), is difficult to remove.

From its composition and properties physicians recognize that "Ovaltine" is especially well adapted to the feeding of growing children, both in health and sickness. The mere fact that when added to a vitamin-free diet it will almost at once set up in a puny, poorly grown, and malnourished animal a growth and development normal in every respect, should in itself carry conviction.

When, however, the results of our laboratory experiments are amply and widely confirmed by the successful use of "Ovaltine" in clinics, and by prominent pediatrists throughout the world, assuredly it may be said that assurance has become doubly sure. The delicious flavour of "Ovaltine" appeals particularly to children, and they thrive upon this perfectly balanced food in a completely satisfactory way. A pamphlet, well illustrated and dealing at length with the scientific tests referred to above, will be gladly posted on request.

A liberal supply for clinical trial sent free on request.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

An Announcement

CAROTENE B.D.H.

Results of recent research (*The British Journal of Experimental Pathology*, Vol. XI. No. 2, April, 1930) indicate that Carotene confers complete immunity against the spontaneous infections occurring in rats fed on a diet deficient in Vitamin A.

Indeed, there is good scientific evidence to show that Carotene is closely related to the growth-promoting and anti-infective factor found in green vegetables, egg yolk and butter.

At the request of a few medical men The British Drug Houses Ltd.—the manufacturers of Carotene—are issuing it in sugar-coated pellets each containing 2 mg. of the pure substance; these pellets are now available to any physician who is desirous of making a trial of this active substance for correcting a deficiency in

Vitamin A

The pellets can be obtained through the principal pharmacists, or direct from the makers, at 6/- per bottle of 50—less the usual discount to medical men.

Medisoap Therapy

The use of Medicated Soaps ensures the proper application of many drugs with the advantage of regular and frequent application, and at the same time attains adequate cleansing of the part. An interesting Brochure, indicating its uses in various skin diseases and describing Midgley's Medisoaps, will be sent on application.

MEDISOAP ICHTHAMOL MIDGLEY

When applied to the skin Ichthamol is partially absorbed, and has a stimulating and mildly irritant action in chronic skin diseases, such as acne and eczema In addition to this useful action, it possesses antiseptic properties. Incorporated in a base of pure superfatted soap it makes available the use of a most valuable agent, possessing healing, sedative and tonic properties. One dozen trial samples (No. 10) sent post free for clinical use to any registered practitioner on application.

MEDISOAP ICHTHAMOL is prepared in three strengths:—

Mild (No. 59) 4% Standard (No. 10) 10% Strong (No. 96) 20%

HOW GIBBS HELPS THE DOCTOR

He can confidently recommend Gibbs Dentifrice as a safe, sure, mild dentifrice for all

Gibbs Dentifrice lives up to all that any Doctor would wish a dentifrice to be and do. He is safe in recommending Gibbs Dentifrice because it is a mild, gentle, yet efficient cleansing agent which will not harm even the most delicate mouth, or scratch the finest enamel.

Gibbs Dentifrice conforms to the findings of the most recent scientific research in the field of dental prophylaxis.

Gibbs Dentifrice approximates the ideal dentifrice, since it meets the following conditions:

It is of a consistency and composition calculated to discourage the further accumulation of mucous plaques and other deleterious material upon and around the teeth; and leaves the surface of the enamel brilliantly polished.

It is non-irritating and harmless in its reaction upon the delicate mucous membrane of the mouth.

It is free of any decalcifying action upon the tooth substance.

It is mildly alkaline and tends to correct any acid reaction in the mouth. It has mildly antiseptic properties which check and retard sepsis in the mouth. These properties also assist in keeping the toothbrush sweet and clean.

It is in a convenient form for use, and has a pleasant taste and flavour; and leaves a clean and refreshed feeling in the mouth.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Gibbs Dentifrice

The Treatment of Pulmonary Affections by Inhalation.

THE AËRISER

This instrument converts liquids into a voluminous but almost invisible vapour, or, in the words of the "LANCET," it "renders fluids like smoke," and thus enables medicated vapours to be inhaled continuously without injury to the delicate mucous lining of the air passages.

In all other sprays, atomisers, inhalers, etc., the spray is given off in palpable particles and cannot be used long without giving rise to discomfort. With the Aëriser, however, solutions, whether aqueous, oily, or balsamic, are given off in such a state of fine division that when the vapour is directed on to a sheet of glass or paper it remains unsoiled; consequently, when inhaled the medicament reaches the whole of the respiratory tract even to the innermost recesses of the lungs without causing the slightest irritation.

Vita-Weat contains every part of the wheat berry

When a diet regime is prescribed it is usual to include Vita-Weat, the British whole-wheat crispbread, in place of soft whole-meal or white bread.

Vita-Weat is an article of diet combining the nutritive and health-giving properties of the best wholemeal bread with the palatability of the white loaf, at the same time ensuring an easily digested product with a high Vitamin, Caloric and Protein content.

It is an all-British crispbread, guaranteed to be made from 100 per cent. stone-ground whole-wheat grown within the Empire. It is of distinctive texture, inviting mastication and insalivation; it has a delicious "crunchiness" and a pleasing ripe-corn flavour; and it contains every part of the wheat berry, nothing whatever being removed in the process of manufacture.

Not the least of the many benefits to be obtained from a regular diet of Vita-Weat is that of intestinal correction and the prevention of many of the intestinal and gastro-intestinal ailments due to constipation.

When forming a suitable proportion of the daily diet, Vita-Weat acts as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

MONSOL
in
MIDWIFERY

The antiseptic employed in midwifery must be both germicidally powerful and at the same time safe and free from danger.

Monsol is the ideal preparation in such cases because:—

(1) *It is selective in its action on streptococcal bacteria, being 10 times as powerful as lysol in this respect.*

(2) *It has a perfectly non irritant action on the tissues and mucous membranes at therapeutic concentrations.*

(3) *It keeps the hands and skin soft and does not roughen them.*

(4) *Is is a standard product and never varies in composition.*

Authorities competent to judge have expressed the considered opinion that the use of Monsol in midwifery reduces the incidence of puerperal sepsis by fully 90%.

Other authorities have also stated that certain lysol and cresylic acid preparations are not efficient germicides against streptococci without being used at concentrations which involve grave risk of injuring the tissues.

Monsol is so bland in action that it can safely be used at strengths far greater than germicidally necessary without any risk of causing irritation.

MONSOL PREPARATIONS INCLUDE:
MONSOL LIQUID, OINTMENT, INTERNAL CAPSULES, PASTILLES, DENTAL CREAM, TOILET SOAP, ETC.

How Science has proved that the best substitute for Mothers' Milk is Almata

When (1) Mothers' Milk and (2) Almata mix with the gastric juice in the Infant's stomach, the effect on the acidity is practically the same in the two cases. But Cows' milk requires over three times as much gastric juice as Human Milk or Almata to render it digestible.

A well-known physician writing in the *Lancet*, showed that Almata alone among the infant foods he examined gave a buffer value approaching that of Mothers' Milk.

Almata is the nearest approach to Mothers' Milk. It is the result of prolonged scientific research.

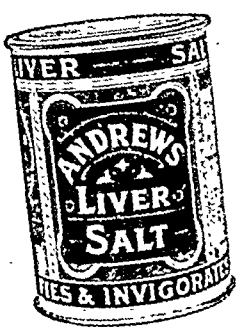
A useful Saline Aperient



Andrews Liver Salt is an ideal Saline aperient of pleasant taste, readily taken and well tolerated by the most delicate adult or child. It ensures an easy and complete evacuation without griping or tenesmus; it is not contra-indicated in the majority of diseases where constipation arises.

It acts by stimulating the intestinal glands, thus increasing the fluid content of the bowel, producing gentle peristaltic contractions and a natural and efficient clearance of the colon and rectum without any unpleasant after effects.

COMPOSED OF

In cases of fever, its brisk effervescing solution in water makes a refreshing and invigorating drink, relieving thirst, diluting the toxins and relieving the strain upon the kidneys.

It may be used as a hydragogue purgative in the treatment of oedema, ascites, pleuritic effusions and nephritis, and with safety even in failing cardiac conditions.

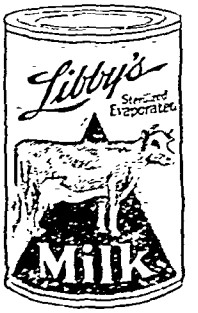
Andrews Liver Salt is prepared with the greatest possible care to secure uniformity of composition, under hygienic conditions and from the purest ingredients obtainable, each batch being tested by our Staff Analyst.

An 8-oz. tin will be sent free on request.

Andrews Liver Salt

SCOTT & TURNER LIMITED, Works and Laboratories at Newcastle-on-Tyne

Natural and normal nourishment *for every baby*



Every drop of Libby's Evaporated Milk contains *all the food properties of milk*, but always *in a* constant and uniform quality. All the vitamins of milk are also present, and the same supplement you would use with any milk—orange juice or tomato juice—assures the presence of the anti-scorbutic vitamin. The process of homogenization breaks up and emulsifies the large fat globules—makes them as readily assimilable by the infant as mother's milk. Sterilization makes Libby's Milk scientifically clean up to the very moment that it reaches the nursery.

The whole day's feeding can be prepared at once and will keep fresh and sweet.

Libby's Evaporated Milk

Libby, McNeill & Libby, Ltd.
(Dept. 22), 8, Gt. Tower St., London, E.C.3

£1,000 *will be paid to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.*

COLLOSOL Argentum (CROOKES)

COLLOIDAL METALLIC SILVER

A product of pronounced bactericidal value, free from staining or irritation to most delicate tissues. Indicated in all forms of sepsis, skin diseases, ear, nose and throat troubles, &c. Of particular value in ophthalmic work and used by upwards of 100 County and Borough Medical Officers in midwifery for infants' eyes at birth. The subject of nearly 50 references in authoritative Medical Journals and Textbooks.

AMYL NITRITE "STERULES"

(MARTINDALE—Regtd. T.M. & Design)

IN BOXES OF 12 "STERULES"

Containing 1, 2, 3, 4, 5, 6, or 10 minims (0.05, 0.1, 0.2, 0.25, 0.3, 0.35, or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving ANGINA PECTORIS, SPASMODIC ASTHMA, MIGRAINE, POST-PARTUM HAEMORRHAGE, HAEMOPTYSIS, SEA-SICKNESS, to ward off EPILEPTIC ATTACKS, etc., and as an ANTIDOTE to CHLOROFORM: it is largely employed in threatened FAINTING and COLLAPSE, and as a RESTORATIVE after GAS in DENTAL OPERATIONS.

Abstracts from the medical literature:

ANGINA PECTORIS: "The best remedy. To lower blood pressure has a more rapid action than any other drug, and is useful in cutting short the paroxysms of pain." —L., ii/05, 325; ii/06, 1335.
"Gave prompt relief in the more pronounced attacks." —B.M.J., ii/06, 304.
"In all spasmodic affections, such as angina pectoris, one of the best remedies."—B.M.J., i/09, 994.
"The nitrites are indispensable."—B.M.J., ii/09, 1122.
"The quickest means of relieving the acute pains." —L., ii/08, 1132.
"Fear of death entirely disappeared."—L., ii/09, 572.
"No drug can compare with Amyl Nitrite."—L., i/09, 240; L., ii/05, 812.

INTRATHORACIC ANEURISM: "For the acute anginal attacks Amyl Nitrite inhalation, followed by internal use of Nitroglycerin or Erythrol Nitrate, is generally efficacious."—L., i/13, 945.

ASTHMA: "In most cases the reduction in blood pressure relieves."—B.M.J., ii/11, 1327.

POST-PARTUM HAEMORRHAGE: "Immediately stopped; no further trouble followed."—B.M.J., ii/06, 1125.

HAEMOPTYSIS: "With few exceptions, promptly effective. Secures peace of mind to sufferers." —L., i/08, 130.
"Some convincing cases in which it saved life." —L., i/07, 930.
"Amyl Nitrite the drug par excellence; acts better the quicker it is used."—Edin. Med. Jl., 1904. L., ii/04, 522, 942, 1446; B.M.J.E., i/06, 79.
"In severe haemoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory."—B.M.J., i/06, 917.

SEA-SICKNESS: Very useful, inhalation repeated every 2 or 3 hours if necessary.

CHLOROFORM SYNCOPE: The quickest means of restoring the heart's action.

INFANTILE CONVULSIONS: Well treated by 1 min "Sterule."

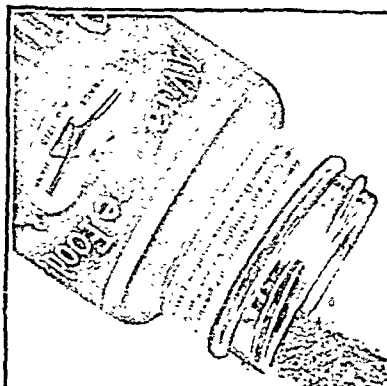
PLEASE SPECIFY MARTINDALE'S AMYL NITRITE "STERULES"

We also supply other vasodilators, e.g.:

MANNITOL NITRATE TABLETS: 1 gr.
ERYTHROL NITRATE TABLETS: ¼, ½, and 1 gr.

W. MARTINDALE,

12, NEW CAVENDISH ST., LONDON, W.1.



'Phone: Langham 2440. 'Grams: Martindale, Chemist, London.

HAY FEVER

Detoxicated Anti-Coryza Vaccine (Genatosan) has proved a successful prophylactic with many patients previously subject to annual attacks of hay-fever. As this vaccine is detoxicated, massive doses may be administered with little or no reaction.

In actual treatment, and also for prophylaxis with hypersensitive and nervous patients, local application of Anti-Coryza Spray Vaccine is indicated.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

The Pre-eminent Vitamin Food

"Bynotone"

"The vitamin problem is of far greater importance than is generally realised . . . . . The vitamin question should first be attended to in the bringing up of infants and young children."—PLIMMER.

"The results of prolonged minor degrees of vitamin deficiency give rise to inferiority in physical development, instability of the nervous system, lack of recuperative power and endurance, and consequent cumulative fatigue and lack of resistance to infection."
McCOLLUM & SIMMONDS

"Bynotone" is a concentrated nutrient rich in the vitamins *A*, *B* and *D* and other elements which, though often deficient in the ordinary everyday dietary, are of vital importance to nutrition.

"Bynotone" contains essentially—bone marrow, yeast extract, hæmoglobin and liver fat; the latter is prepared by a special process and is the richest known source of vitamin *A*. The natural vitamin content of the ingredients of "Bynotone" is augmented by the addition of a proportion of synthetic vitamin *D*.

"Bynotone" is the ideal accessory food during the ages of active growth and adolescence, the periods of expectant and nursing motherhood and the stage of convalescence after acute disease.

It is a nutrient, hæmatinic and restorative which assists the assimilation of other foods and promotes general good health.

Vitamins A.B.&D.

(*Aesculapius*)

HYPERACIDITY

In the treatment of hyperacidity, the orthodox method of neutralizing with alkalis is accompanied by certain unpleasant sequelae, such as the evolution of gas in the stomach. Another method is to utilise the phenomenon of adsorption, in which the acid is adsorbed on some substance without being chemically neutralised.

COLLUMINA

The special Colloidal

Aluminium Hydroxide

prepared at Evans' Biological Institute is peculiarly adapted for this purpose. COLLUMINA absorbs the acid without splitting it up, thereby obviating its painful effects without unpleasant results.

In addition to its neutralizing effect upon hydrochloric acid, COLLUMINA is a mild astringent and deodorant, thereby presenting usefulness in the relief of congestion of the mucous linings of the mouth, pharnyx, and stomach, and, although mildly astringent, is soothing. It is non-toxic and, being pleasantly flavoured, finds a wide range of usefulness varying from conditions of genuine organic disturbance to hypochondriacal conditions.

COLLUMINA is supplied as the plain colloidal preparation of aluminium, and also combined with phenolphthalein, for cases of intestinal stasis, and with bismuth for cases associated with intestinal colic and diarrhoea.

Sample and literature on application to

Evans' Biological Institute, Runcorn.

PORTRAIT IN MOSAIC OF THE EMPEROR JUSTINIAN, WHO, WITH THE EMPRESS THEODORA, RULED THE CIVILISED WORLD IN THE SIXTH CENTURY.—Amid the confusion that accompanied the formation of a new centre of civilisation in Byzantine Constantinople, pioneer influences were already at work in the reign of Theodosius II. It was, however, chiefly the unifying energy of Justinian and his Consort that welded the various elements of civilisation into what we know as the Byzantine, which became the guiding force in the world. Justinian is remembered best perhaps in connection with the *Corpus juris civilis*, on which the law of most European countries is based. This great codification was carried out by his orders and under his inspiration, and this accomplishment may well be regarded as one of the most fruitful acts for the progress of humanity. Justinian instituted a reform of legal studies by which it was ensured that teaching should be in the hands of properly qualified persons, and his measures relating to slavery are much in advance of those of his predecessors. In his relations with the barbarian world, Justinian introduced a civilising influence.

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

A new building furnished with Baths and all modern Electrical Appliances for treatment was opened last Saturday, April 26th.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 1 grain of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures:—

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest.
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable. The Spa is under medical supervision and close co-operation is maintained with the patient's own physician.

Further particulars may be obtained at Belle Vue Spa or 7, Harley Street, W.1.

A Lecture
ON
TREATMENT OF MAMMARY CARCINOMA BY RADIATION.*

BY
SIR G. LENTHAL CHEATLE, K.C.B., F.R.C.S.,
SURGEON TO KING'S COLLEGE HOSPITAL.

THE two objects of this article are, first, to describe how pathological observation shows that the whole of the breast itself should be radiated in carcinoma of that gland, and, secondly, to describe the method I adopt in delivering interstitial radiation to a breast containing carcinoma. Before embarking on these two subjects it is essential to make some observations on radiation of carcinoma in general.

Biological Effects of Radiation.

Treatment of carcinoma by radiation is in an exceedingly tentative and experimental state. All careful workers upon the subject deplore exaggerated hopes of success in all examples of carcinoma.

The energy discharged from a needle containing 1 mg. of radium element is terrific. At present we are judging our results from the effects of doses that may be a great deal too large and administered for too long a period at a time. If little or no result is detectable from a given dose, larger doses are employed, when, for all that is at present known, smaller doses frequently delivered in short periods at frequently repeated intervals might be more successful.

If Moppett's observations on x rays of different wave-lengths are correct they open up the question whether x rays may eventually prove of greater value than radium. Moppett has isolated wave-lengths that retard and those that stimulate growth. A proper manipulation of the wave-lengths of x rays that retard growth may replace all other forms of radiation therapy.[1]

Boveri said that "normal cells produce malignant cells under the influence of x rays and radium and malignant cells in the same way (by means of x rays and radium) produce cells that are no longer able to live."[2] Radium emanation may also possess wave-lengths differing in the effects they induce. Boveri's statement would make the treatment of even a localized carcinoma a matter of anxiety were it not for the fact that the induction of carcinoma by means of radiation requires small doses spread over a very long period of life.

The success which external radiation has at present attained has been gained when the disease has been comparatively superficial and not deeply infiltrating, and also in the treatment of highly radio-sensitive tumours. Success of interstitial radiation has been attained when the carcinoma has been strictly limited to a localized area. In some instances, however, when these necessary provisions have been present, disappointments after external and interstitial radiation have arisen and damped the ardour of even the most enthusiastic practitioner. The failure in these instances may depend upon the error of underestimating the extent of the area that should be radiated. There are many other factors about which knowledge is at present incomplete; these are so little within our conception that all forms of radiation are thereby placed in a highly speculative position. When all the essential factors are known it must be hoped that they can be successfully applied or overcome as may be.

There remains the reverse side of the picture—namely, the application of radiation to those carcinomata that have spread to such a degree that the disease is no longer localized in the immediate area in which it began, but has spread more extensively in that area and has also reached other parts of the body. All means of radiation are at present unable to prevent the death of a patient in whom a carcinoma has reached these stages.

At this point it would be well to describe shortly what is meant by (1) external and interstitial radiation, and (2) the radio-sensitivity or radio-resistance of tumours.

*Delivered to the Yorkshire Branch of the British Empire Cancer Campaign, February 4th, 1930.

External and Interstitial Radiation.

The method of external radiation is the application of the source of radiation at a distance from the affected parts. The source of external radiation may be either x rays or radium. External radiation can be delivered by the so-called *radium bomb*. On the Continent, where treatment by means of radium bombs has been compared with that by x rays, opinion on the whole does not consider that one method possesses greater sterilizing powers than the other, and that x rays are more generally and more cheaply available.

The method of interstitial radiation is the direct application of the source of radiation to the tissues so that it is in actual contact with them. The source of interstitial radiation is either radium element or its emanation. The interstitial application of x rays is at present impracticable.

Radio-Sensitivity.

The radio-sensitivity of a tumour is manifested by its regression after a given dose of external radiation. When rapid regression of a tumour occurs in these circumstances it is a radio-sensitive tumour. From this point of view the treatment of highly radio-sensitive tumours would be solved were it not for the fact that these tumours are usually the most malignant, and therefore are accompanied by wide and rapid diffusion over the body. Lympho-sarcoma, carcinoma of the base of tongue, tonsil, and nasopharynx, and certain types of breast carcinomata belong to this category.

The rapid disappearance of a lymphosarcoma of the mediastinum or a transitional-celled carcinoma in the lymphatic glands of the neck after external radiation does not depend on the method of radiation so much as on the great radio-sensitivity of these tumours. Certain tumours that are not highly radio-sensitive regress under external radiation provided they are superficial and not too deeply infiltrating. The explanation of this fact is that the whole of these tumours is so close to the source of radiation that their resistance is overcome. Examples of squamous epithelioma and rodent ulcer come in this category. A highly radio-sensitive tumour will regress whether it be superficially or deeply situated, provided all its cells are within the range of external radiation. The cells of radio-sensitive tumours which cannot be reached by external radiation—that is, metastatic growths—are more likely to be inaccessible to interstitial radiation and also to the process of excision.

A tumour is described as being radio-resistant when it exhibits little or no signs of regression after it has been subjected to a given dose of external radiation. The subject of my paper—namely, carcinoma of the breast—as a rule belongs to this category. Nearly all malignant tumours, whether radio-sensitive or radio-resistant, regress on interstitial radiation, the reason being that the tumour cells of radio-resistant tumours are so close to the source of radiation that their resistance is overcome. External and interstitial radiation may induce the same changes or a modification of the same changes in the tumour, or the effects of an interstitial radiation may be more destructive in action.

Reaction of Surrounding Tissues.

While it is certain that the regression of a tumour after radiation depends on the effect of radiation on the tumour cells, there is also a considerable body of evidence that yet another factor involved is to be found in the reaction of the tissues in which the tumour lies. Dr. W. Cramer was the first to point out that the changes in the stroma which follow on radiation play an important part in the process which leads to the regression of the growth.[3] More recently J. C. Mottram has adduced experimental evidence bearing on this point.[4] He subjected transplanted tumours growing in mice to a dose of radiation known to be sufficient to produce regression of this tumour. He then transplanted these radiated tumours in gradually increasing intervals after radiation (one, two, three, four, five days, and so on) into fresh mice. He found that the tumours which had been removed and transplanted one or two days after radiation grew almost as well as a normal non-irradiated tumour, but if the irradiated tumours were

removed and transplanted after a longer interval their growth in the new mice was at first much less active, and eventually they failed to grow altogether. This experiment shows that it was the prolonged presence of the radiated tumour cells in the organism of a radiated mouse which contributed to the lethal effect of radium. He attributed the effect on the organism of the host to an effect on the blood vessels. Other evidence which may be quoted is that of Russ, who showed that preliminary radiation of the skin inhibits the growth of a tumour subsequently transplanted underneath the irradiated area. Moreover, it is claimed that the dosage of radiation necessary to render the malignant cells of a transplantable tumour inert *in vitro* is much greater than that required to produce regression of the same transplantable tumour *in vivo*.

When it is considered that a trespassing malignant epithelial cell possesses no blood supply of its own, and that its maintenance depends upon the amount of nourishment it can obtain from the tissues into which it has trespassed, then the metabolic, biological, and trophic changes in these tissues may be of vast importance. The detrimental effect upon the radiated tissues in which the malignant epithelial cells are present has been ascribed either to deprivation of blood supply or to the constricting effect of cicatricial tissue that kills the epithelial cells by the pressure it exerts. There are many reasons that appear to me to render these explanations untenable. I will mention only one which seems to me to show that normal tissues can resist, at all events temporarily, the extension of rodent ulcer. The lines at which rodent ulcers often become arrested correspond to the boundaries of nerve areas.[5] There is no mechanical, blood vascular, or lymphatic vascular arrangement that can arrest growth at these boundaries.

At present the precise relationship of this clinical observation to the failure of radiated tissues to allow the growth of transplantable tumours in them is not clear. The only merit of calling attention to the point is that it is another example of some inexplicable power possessed by the tissues of being able to resist the invasion of a growing epithelial tumour. I may say here that Dr. Cramer has produced experimental evidence that coincides with my clinical observations.[6]

RADIATION OF THE BREAST.

I will pass on to the first object of my paper and show how all my pathological investigations impress upon me the importance of exposing the whole breast to radiation, and not only that part of it containing the palpable lump. It appears to me illogical to radiate the axilla, subclavicular and supraclavicular regions, and intercostal spaces without radiating the whole breast itself. Clinical evidence alone cannot be trusted to indicate the area occupied by carcinoma in the breast. The only clinical feature that can possibly act as a guide to the area that should be radiated in the breast is the lump of disease in the gland.*

The lump in the breast consists of two parts that vary enormously in proportion to each other in different examples, and most frequently there is no clinical guide as to which of the two is predominant. The two parts consist of the primary epithelial neoplasm within ducts or ducts and acini, and the secondary epithelial invasion that has taken place from these sources. Frequently the lump consists chiefly of epithelial cellular invasion and a small area only of the primary growth. On the other hand, although the lump may be large the chief mass of it may consist of the primary epithelial neoplasm contained within normal but distended boundaries of ducts or ducts and acini. Even when the lump chiefly contains epithelial cells that are invading the connective tissue in the breast outside its ducts and acini, the primary epithelial neoplasia confined within normal boundaries may be more extensive than is generally supposed. It would be fatal if radiation failed to include all the primary epithelial neoplasia within its sphere of action as well as all the invading cells.

*Fallibility of clinical signs also applies to the axillary regions in fat and thin women. In thin women the failure to detect enlarged lymphatic glands in the axilla is an indication of importance that they may be free from carcinoma. It is not an infallible test, however, for, as I have pointed out, the axillary lymphatic vessels at the point where they pass over the upper limit of the first rib may contain carcinoma when all the lymphatic glands in the axilla are free from the disease. It is a rare condition.

Schimmelbusch's Disease.

At this point I must draw your attention to "Schimmelbusch's disease," unfortunately called by most people "chronic cystic mastitis." It is an important disease, because about 20 per cent. of all carcinomata begin in this lesion, which may be present in areas widely separated from each other in different parts of a breast.

The complete disease—that is, when carcinoma ensues—manifests itself in three decades in the patient's life. The first stage begins in the late 20 and early 30 years of life, and consists of a specific and typical desquamative epithelial hyperplasia. In this stage there is only the formation of cysts. The second stage corresponds to the late 30 and early 40 years of life; the desquamative process now begins to change, and when completed has actually changed into a benign epithelial neoplasm. At the end of this stage papillomatous tumours and tumours devoid of connective tissue elements fill and distend the affected ducts and acini. The third stage has been reached when usually at one part only the epithelial neoplasia has passed into the state of carcinoma, from which epithelial cells invade tissues outside the normal boundaries of ducts and acini. This fatal alteration in the nature of the epithelial neoplasia begins in the late 40 and early 50 years.

Schimmelbusch's disease may be confined to a small area of terminal ducts and their acini, or it may involve the whole tract of only one large duct, all its branches, and their acini. Moreover, two or more areas may be affected microscopically in the same breast. Clinical evidence of the extent of the area occupied by this disease is unfortunately very obscure and untrustworthy. From many points of view Schimmelbusch's disease is of practical importance in its relation to the area of a breast that should be radiated. It is true that it conforms to the usual experience in carcinoma of the breast in general—that is, that carcinoma as a rule appears in only one part of a breast, although epithelial cells may escape from the primary epithelial neoplasia in ducts and acini from many foci in that part.

I have specimens of only three breasts suffering from carcinoma arising in more than one segment. In two of these this multicentric origin occurred in Schimmelbusch's disease situated in widely separated parts. In the breast of the remaining specimen there is no sign of Schimmelbusch's disease.

Reasons for Radiating the Whole Breast.

It may be urged that, if carcinoma so commonly begins in only one part, why should it be so essential to radiate the whole breast? There are three reasons. First, it is impossible to say how far the escaped epithelial cells have disseminated in the breast; secondly, there may be other unknown parts of the gland which may contain epithelial neoplasia still confined within normal boundaries, and which in the course of time may end in carcinoma; and, thirdly, upon clinical examination alone it is rarely possible to know whether the carcinoma began in Schimmelbusch's disease.

It might be argued that, carcinoma having occurred in one place, epithelial neoplasia is not likely to become malignant in another. Dr. W. Cramer was the first to show that when a tar carcinoma has been removed from one part of a tarred cutaneous surface, a fresh focus of carcinoma may rapidly appear in another part that was previously not carcinomatous; and Dr. A. Leitch has shown that a limited application of tar which produces no immediate result may be followed at a long interval by carcinoma. These experiments convince me that it is not safe to leave in the breast an epithelial neoplasm that may be or may become malignant. From what I have said about the decades of life in which the sequence of events occur in the complete Schimmelbusch's disease, it can be understood that the occurrence of carcinoma in another focus of Schimmelbusch's disease in the same breast may take a considerable time in developing. Everything points to the necessity of radiating the whole gland, and not only the part that is clinically carcinomatous.

The remaining point that arises is that if radiation of the whole gland is indicated when Schimmelbusch's disease has ended in carcinoma, then why not radiate the whole of all cystic breasts as a preventive measure? I agree that if radiation is proved to be a successful form of treatment in epithelial neoplasm which is not malignant, the answer to this question would be that a complete radiation of all cystic breasts would be a wise precaution.

I have five breasts that bear upon the necessity of radiating the whole and not a part of the breast in carcinoma of that gland. The five breasts are rare examples of the disease. In all of them the whole epithelium of the breast in all the larger ducts, their branches, and their acini, has undergone epithelial neoplasia of a malignant-looking type. In the first specimen the whole of the epithelial neoplasia has undergone regression, and there is no microscopical evidence of carcinoma in the gland. The breast was thin, yet there was no clinical evidence of any pathological change in it.

The second specimen was also a thin breast. The whole of the epithelial neoplasia which looked malignant had undergone regression, except at one part where carcinoma had occurred and spread to a lymphatic gland in the axilla. The state of this lymphatic gland was the only clinical evidence that there was anything wrong with the breast.

In the third specimen the epithelial neoplasia has not undergone regression at any part, and from one duct, its branches, and its acini, epithelial cells have escaped and become diffuse over one quadrant of the gland, and also have heavily involved the rest of the body. The epithelial neoplasia, which affected the whole gland, gives all the morphological appearances of being of a highly anaplastic type. The extensive widespread diffusion of its cells confirms the morphological appearances. Clinical evidence of the carcinomatous part was abundant. There was no clinical evidence of the pathological state elsewhere in the breast.

In the fourth and fifth specimens the whole of the breast epithelium has been replaced by carcinoma, and the morphological appearances suggest that the whole of the epithelium of the breast has become carcinomatous. There was also widespread diffusion over the body, although the morphological appearances were not of so highly an anaplastic type as that in the third specimen.

There are many early examples in which radiation of the part of the breast that contains the lump would probably include the epithelial neoplasia in the terminal ducts and acini as well as the mass of invading cells that have escaped from it. There are no clinical signs that can indicate to the operator whether he is or is not dealing with such a localized distribution of disease.

Many examples occur in which radiation of the part of the breast that contains the lump would certainly not include either a dangerous-looking epithelial neoplasia in ducts and acini or the cells that have invaded the connective tissue of the breast outside them. For example, the lump in the breast illustrated in Fig. 1 was clinically recognizable as being a large one, and the enlarged glands in the axilla confirmed its carcinomatous state. There was no clinical evidence of extension of the dangerous-looking epithelial neoplasia in the ducts and acini that extended to the limits of the breast in the opposite direction. The epithelial neoplasia inside these ducts and acini has undergone gelatinous (colloid) degeneration, and there are also carcinomatous cells in the connective tissue outside them.

It may be said that it is exaggerating matters to found a system of radiation upon advanced cases of this kind. The answer to such a criticism would be: first, that there are no clinical signs by which a localized carcinoma can be distinguished from one that is diffuse; secondly, for all that is known the extent of the disease may have been always widespread and the lump a later manifestation: thirdly, evidence of wide extension is detectable only by microscopical examination; fourthly, there is no general correlation between the extent of the area occupied by the disease and the size of the lump or the length of time it has been noticed.

Clinically Undetectable Tumours.

I pass on to another clinical type of carcinoma of the breast which will arise in treatment by interstitial radiation. The example is as follows.

The woman was 42 years old, and a tumour she had noticed in her right axilla had been removed and proved microscopically to be carcinoma in a lymphatic gland. The woman was fat, and there was no clinical sign of a tumour in the breast. The right breast and the rest of the axillary glands were removed, and microscopical sections were cut of the whole breast. At the margin of the gland the carcinoma was discovered after many whole sections of the breast had been cut and examined; it conformed to the general contour of the gland, and malignant-looking epithelial neoplasia also occupied a wide tract in the affected duct and its branches.

In this particular instance the tumour in the breast could not be detected by clinical examination. It was discovered during a complete microscopical examination of whole sections. Belonging to this clinical type are those instances in which enlarged axillary lymphatic glands lead to the detection of a very small primary tumour in the breast after a careful clinical examination. Radiation of the breasts belonging to this type may be considered from the following point of view. The rapid and wide diffusion of the growth indicates the presence of a highly anaplastic tumour, and therefore probably one that is radio-sensitive and would regress under external radiation. I should regard this particular clinical type as being an example in which treatment by external radiation should be first attempted, for the following reasons. The cases are inoperable from the point of view of cure. Sometimes breasts belonging to this clinical type weigh 3½ pounds. Interstitial radiation of these breasts would necessitate a dose that might be constitutionally dangerous as well as difficult to apply, and there is the clinical indication that the tumours belong to the radio-sensitive type.

A hard, solid, defined lump beside the nipple, and making it lean to one side, is generally a sign that the chief part of the breast is occupied by carcinoma. The following case is of practical importance.

The woman, aged 42 years, was married; she complained of an intermittent spontaneous discharge of blood from the nipple, beside which was a lump pushing it to one side. Whole microscopical sections proved that the lump beside the nipple was a metastasis from a carcinoma originating in the terminal ducts and acini at the outer margin of the gland, the presence of which was not indicated by any clinical signs. There was also a dangerous-looking papilloma, the cells of which were still confined within normal boundaries in the main branch of the duct leading into the carcinomatous epithelial neoplasm in its terminal branches and acini. This was the source of the metastasis beside the nipple and the haemorrhage from that structure. The complete radiation of this breast could have offered the only chance of success by means of that treatment.

Paget's Disease of the Nipple.

The evidence revealed by the systematic examination of whole microscopical sections made from the underlying breast in Paget's disease of the nipple proves that carcinoma can be present in breasts without causing a lump or any sign of its presence, and without any axillary lymphatic glandular involvement. A proportion of breasts underlying Paget's disease of the nipple contain no carcinoma, but, so far as my experience goes, they all somewhere contain a dangerous-looking epithelial neoplasm, sometimes in a large duct and at other times in distended terminal ducts and acini in two or more parts of the breast. The only wise plan is to subject the whole of all breasts suffering from Paget's disease of the nipple to interstitial radiation if they are to be radiated at all. I am speaking of the treatment of the underlying breast only in Paget's disease of the nipple. I do not know whether the cutaneous disease is affected by radiation. External radiation by means of *x* rays was quite unsuccessful in one case of mine.

Radiation versus Radical Operation.

The axillary, supraclavicular, and intercostal regions and the subcutaneous tissue of the chest should be radiated in every case, however localized to the breast the disease appears to be. The radical removal of an operable carcinoma of the breast will always be safer than an inadequate radiation of the gland. By the radical operation the whole of the carcinomatous area will be removed with certainty, and so will all potentially dangerous epithelial neoplasia that may exist elsewhere in the breast. There are, indeed, many observers who believe that in the present state of knowledge and experience the surgeon who embarks upon interstitial radiation only of a breast in which carcinoma is possibly completely removable, is taking upon himself a great responsibility. This statement will meet with general agreement. On the other hand, the treatment of carcinoma of the breast by means of radium will be of

comparatively little use unless it is completely successful in the sterilization of the earliest phases of carcinoma in that gland. I have begun my investigations in this subject by buying radium of my own and using it in a tentative manner upon those patients with early carcinoma who refused excision and those who were physically unfit on account of age or decrepitude for an operation of great magnitude. The results of five cases I have been able to treat so far support the conviction of Mr. G. L. Keynes,[7] who believes that interstitial radiation is the operation of choice in the treatment of early carcinoma of the breast. So far as my experience has gone—and it has lasted only a few months—the tumours in the breast have melted away and have left no signs of their previous existence.

Secondary deposits in tissues outside the breast sometimes seem to be more obstinate in their resistance to interstitial radiation. It may not be that they are more radio-resistant. Their failure to disappear may be due to inefficient radiation. Radiation of secondary deposits is not so practicable, nor is it always possible to radiate safely and at the same time efficiently. The evidence thus gained may in the course of years lead to decisive conclusions. The final treatment by radiation will emerge after experience gained by the use of external radiation alone, of interstitial radiation alone, and by the combined use of external radiation and interstitial radiation.

Before considering the definite treatment of a carcinoma of the breast by means of radiation, the question arises whether a preliminary test of its radio-sensitivity by means of external radiation should be made. In the first place, if a tumour regresses rapidly after external radiation there is no need to consider the application of interstitial radiation, and excision is definitely contraindicated. The disease being highly radio-sensitive indicates that it is also highly anaplastic, and has therefore spread beyond all reach of surgical procedures. On the whole, the fact that so few carcinomata of the breast are radio-sensitive suggests that it would be wasting valuable time (about three weeks) to subject them to this preliminary test.

INTERSTITIAL RADIATION OF BREAST TUMOURS.

The present aims of interstitial radiation by means of the radium element are as follows: (1) To arrange the needles so that a small dose can be delivered evenly over the whole gland for a comparatively long time. (2) To arrange the needles so that the dose of radium element they contain cannot damage the skin to a great degree. Damage cannot be avoided in all instances. (3) To examine the blood before treatment so that the result of the examination may act as a standard by which subsequent changes may be estimated during treatment. The relevant data are the number of lymphocytes and polynuclear leucocytes, the shape, size, and number of red blood corpuscles, and the amount of haemoglobin. (4) The x-ray photograph of a chest may indicate the extent to which it may be involved by metastases.

The most difficult object to attain is the uniform distribution of the dosage. The breast is often a very mobile gland, and needles inserted with the breast in one position may be entirely disarranged when the breast assumes another position. The best method I find of controlling this disadvantage is to support a mobile breast in position while the needles are being inserted. An assistant holds it up in position by means of his thumbs and forefingers. Afterwards, if the breast is not kept in position by the needles themselves, it is controlled by means of carefully applied strapping.

The size of the breast affords another problem in interstitial radiation. A breast weighing 2½ to 3½ pounds consists chiefly of fat, and the glandular elements may be scattered in branches of connective tissue that are widely separated from each other by adipose tissue, or the gland may be more compact and an enormous collection of fat may surround it. There are no clinical means by which the arrangement can be discovered. The dosage of radium element to so large an area might be more than the blood could tolerate with safety unless it were administered piecemeal. In inoperable carcinoma of this kind I have adopted either this piecemeal treatment or I advise treatment by external radiation, hoping that the tumour may be radio-sensitive

Technique of the Method.

At the present moment I possess 80 milligrams of radium element, distributed in twenty-nine needles varying in length. The radium element is distributed as evenly as possible throughout their whole lengths. Their filtration is 5 mm. of platinum.

3 needles	8¾ cm.	of active length	containing	5 mg.	each.
6 ,,	7 cm.	,,	,,	4 mg.	,,
7 ,,	6 cm.	,,	,,	3 mg.	,,
7 ,,	4½ cm.	,,	,,	2 mg.	,,
6 ,,	3 cm.	,,	,,	1 mg.	,,

I make a great point of first fixing the ultimate position of the three longest needles. They are always inserted as the central needles of the bottom layer. They are too long

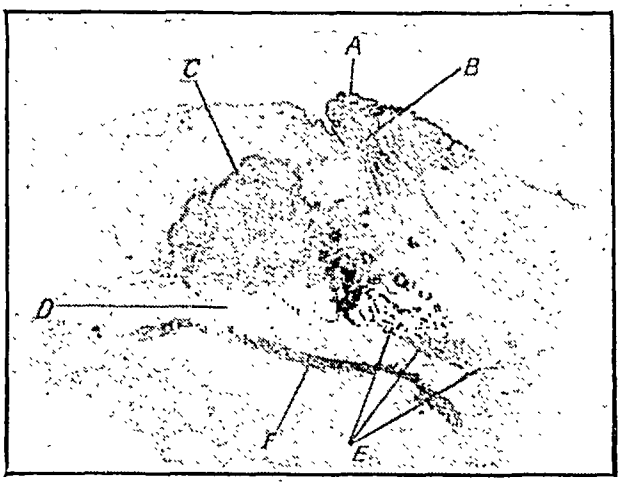

FIG. 1.—Whole microscopical section of an inoperable carcinoma of the breast. A, The nipple. B, The final position of the top of the radium needle inserted through the centre of the nipple. The radiation from this needle will include the disease if it has spread into the lymphatic vessels around the ducts or in the muscular walls of the ducts. In this specimen these regions are free from disease. C, The lump that was clinically obvious. D, The submammary connective tissue. E, The epithelial neoplasia contained in ducts and acini which looked malignant and in parts had undergone gelatinous (colloid) degeneration. F, The pectoralis major.

and slender to place in position without the aid of trocar and cannula. I have three of the latter. I introduce them and keep them in position while I insert the rest of the bottom layer of needles. All the needles in the bottom layer are inserted parallel to each other in the posterior part of the breast, so that subsequent radiation will include the posterior part of the breast, the submammary connective tissue, and upper fibres of the pectoralis major muscle.

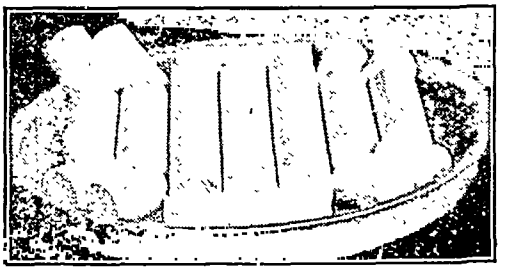

FIG. 2.—The arrangement of the bottom layer of needles in large inoperable case of carcinoma of the breast.

In the next layer the needles are arranged parallel to each other and at right angles to the bottom layer. Whether three layers of needles are inserted depends upon the size of the breast. The centre of the nipple is perforated by a needle which is left in such a position that the situation of its eye corresponds to the base of that structure. Special attention is paid to the lump by passing additional needles through it and around its circumference. Lastly, the three long needles are passed into the three cannulae, which are then withdrawn, leaving the needles in position.

In order to help me gauge the number of needles and the position they should occupy I adopt the following method. I measure the circumference of the breast and mark the measurement on a clay surface. I have twenty-nine cylindrical blocks of wood which correspond in length

and circumference to the area of radiation of each of my needles. The size of these blocks of wood represents an area of 1 cm. in all directions. By arranging these blocks of wood I can estimate very nearly the number of needles I shall require, their position, and their distances from one another.

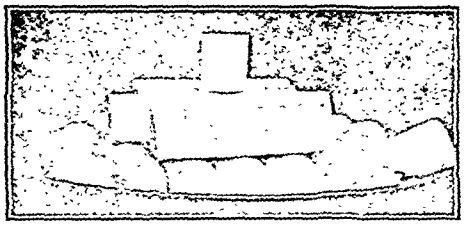

FIG. 3.—The second tier of needles arranged at right angles to those in Fig. 2, and the position of the needle in the central position among the upper ducts.

Figs. 2 and 3 represent the position of the needles in a recent attempt I have made to radiate the whole of a large breast that contained an inoperable carcinoma. The breast was so large that all my needles were employed upon the breast alone. The disease that had spread into other regions was radiated at a later time. As experience proceeds I am more and more tempted to fix the position of the needles by a preliminary insertion of cannulae. Fig. 2 represents the distribution of the bottom layer of the blocks, and Fig. 3 the distribution of the upper layer and the position of the needle inserted via the nipple (see B, *Fig. 1*). The blocks representing the distribution of the needles to the tumour in the breast are not shown.

Turning to interstitial radiation alone in the treatment of an excisable carcinoma in the breast, the problem seems to me to resolve it-elf into two chief questions: (1) Can a whole breast be efficiently radiated by this method? (2) Will time prove whether the regressions of the tumours are permanent?

Turning to the treatment of an excisable tumour, there can be no doubt that the properly conducted operation removes the disease, the breast, and a great deal more tissue than is necessary if the disease be completely limited to the breast, a state of affairs that is unrecognizable clinically. So far as subsequent microscopical examinations, together with clinical histories, can prove the existence of such localized carcinomata, I consider that tumours of this kind have been completely excised.

Finally, I desire to pay my tribute of gratitude to the pioneer work of Mr. G. L. Keynes,[7] to which I have already alluded, and to the work of the staff of Westminster Hospital.[8] I owe Dr. W. Cramer my thanks for his kind assistance in the experimental evidence contained in this article.

THE MECHANISM AND TREATMENT OF PROSTATIC OBSTRUCTION.*

BY

KENNETH M. WALKER, F.R.C.S.,

SURGEON IN CHARGE OF GENITO-URINARY DEPT., ROYAL NORTHERN HOSPITAL; SURGEON TO ST. PAUL'S HOSPITAL.

THE French urologist Leguen recently remarked that in the domain of urology the mechanical element plays an unimportant role, and that it is to the dynamic element that we must devote our attention if we wish to understand why an organ has ceased to function satisfactorily. There is no better example of this than that supplied by a study of the pathology of hydronephrosis. For years we have been trying to explain cases of hydronephrosis mechanically, and often we have been sorely puzzled because, although we could find a mechanical obstruction to the passage of urine in a great number of cases, there were others in which, search as we might, no obstruction could be discovered. Abnormal renal vessels, adhesions around the ureter, and ureteric strictures were pressed into the service without avail; there still remained cases of hydronephrosis that could not be explained. And then, with a change in our mental attitude and an increase of refinement in our methods of examination, it became apparent that the structural alterations in the kidney, known as hydronephrosis, might be the effect of a disordered function of that organ. By pyeloscopy it was shown that a disturbance of the peristaltic reflex, that propels the urine from calyces to pelvis, and pelvis to ureter, might lead on to the development of a hydronephrosis, and that, in the words of Leguen, dynamics rather than mechanical obstruction explained its etiology.

It has occurred to me that it might be interesting to apply the lesson that we have learnt from hydronephrosis to the study of *prostatic obstruction. Is it possible that* in addition to the mechanical there is also a dynamic or neurogenetic factor in the causation of retention following prostatic enlargement? The subject is too intricate to allow of its full discussion in this short paper, but it will nevertheless be of interest to touch on a few salient points. As an introduction it will be advisable to deal first with the mechanical theory of prostatic obstruction.

The Mechanical Theory.

On one point all authorities agree—namely, that no relation exists between the degree of enlargement of the prostate and the severity of the symptoms it occasions. Formerly an attempt was made to explain this anomaly by blaming the middle lobe. It was said that when retention was caused by a prostate which on rectal examination felt only slightly enlarged, the retention was the result of a hypertrophied middle lobe that was pressed down on the internal meatus in the manner of a ball-valve. But a more careful study of cases of prostatic obstruction has shown that the middle lobe is of less importance than was formerly supposed, and that in a great many cases of retention it does not exist. Moreover, as Swift Joly has pointed out, the type of micturition that occurs when an undoubted ball-valve exists, say, in the shape of a pedunculated papilloma growing at the bladder neck, is quite different from that observed in cases of prostatic obstruction. In these true ball-valve cases micturition is either impossible or else unimpaired: there is never, as with prostatic enlargement, only a moderate degree of difficulty.

The ball-valve explanation of retention being unsatisfactory it is necessary to find another. Many theories have from time to time been put forward, but to my mind the most satisfactory is that published by Swift Joly in the *Proceedings* of the Royal Society of Medicine of 1923-24. This theory aims at explaining the retention that follows enlargement of the prostate by the ordinary laws of hydrostatics, but in order that it may work two conditions must be present. The first condition that must be satisfied is that there exists an intravesical projection of the growth which raises the internal meatus above the level of the bladder base; the second, that the tissues are sufficiently *soft and free from infiltration to allow of their being* moulded by slight alterations of intravesical pressure. Granted these conditions, Swift Joly explains retention by the action of urinary pressure on the intravesical projection. He points out that the increase of pressure caused by contraction of the bladder is exerted at right angles to its walls. It is therefore directed downwards and inwards towards its axis—that is to say, towards the

* A paper read before the West Lancashire Branch of the British Medical Association.

urethra. This pressure can be resolved mathematically into two components—a horizontal and a vertical, the horizontal acting at right angles to the course of the urethra and the vertical parallel to it. The horizontal component is directed from all sides towards the upper part of the urethra and tends to close this tube. In Swift Joly's words, "It has exactly the same effect as if an elastic band was stretched round the intravesical projection of the prostate, and the amount of compression that the urethra sustains is directly proportional to the tension and thickness of the band, and inversely proportional to the resistance of the prostatic tissue to distortion." The constricting force, of course, depends on two factors—namely, the intensity of the intravesical pressure and the size of the intravesical projection.

So far we have considered the intravesical projection in its simplest form—namely, as a cone-shaped swelling with the urethra opening at its apex. But this is not the usual form of intravesical prostate. As a rule the urethra opens into a hollow in the cone, which Joly aptly likens to the crater of a vulcano. Now since there is fluid on each side of the rim of this crater the constricting force is partially balanced by the presence of the fluid within the crater itself. It is therefore only the closed urethra below the level of the crater that is subjected to the full action of the constricting force. For this reason the effectiveness of an intravesical projection in causing retention depends on the height of the closed portion of the outlet (see Fig).

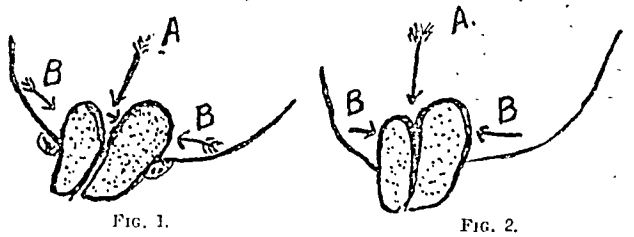

FIG. 1. FIG. 2.

Swift Joly's Theory of Prostatic Obstruction.

FIG. 1.—Intravesical projection, open variety.

FIG. 2.—Intravesical projection, closed variety. A, Longitudinal component acting along urethra. B, Transverse component acting across and compressing the urethra.

Swift Joly's ingenious theory of the mechanism of prostatic obstruction explains many of the anomalies we encounter. It helps us to understand why the size of the prostate is of so little importance compared with its form, and it does this without having recourse to a middle lobe. It also shows that it is the height of the intravesical projection that is the important factor in the production of difficulty, and more particularly the height of the "closed" portion of the projection. If the lobes of the prostate are separated by such deep clefts that much of the intravesical projection remains open, the greater part of it will be ineffective and little difficulty will result. If the bladder outlet is surrounded by a continuous ring of prostatic tissue and is easily closed by lateral pressure the difficulty will be great.

Will Joly's mechanical theory of prostatic obstruction explain all the cases we meet with in practice, or will it be necessary, as Legueu asserts, to fall back on a dynamic factor? Before attempting to answer this question it will be advisable to describe as briefly as possible the dynamic theory of prostatic obstruction.

The Dynamic or Spasm Theory of Obstruction.

As long ago as 1902 Janet called attention to the fact that the act of micturition is subject to certain inhibitions that may be regarded as normal. It is well known that to a man with the penis in a state of erection micturition is impossible. This is not due to the fact that the prostate is congested and swollen (there are many conditions associated with congestion of the prostate in which micturition is only slightly interfered with), but to a spasm of the sphincters and an inhibition of bladder contraction. In addition to this genital inhibition there exists also a reciprocal inhibitory action between the bladder and the rectum. A loaded rectum causes difficulty in micturition, and, conversely, a distended bladder difficulty in defaecation, the action being through the central nervous system, and not, as has sometimes been supposed, by direct pressure. These reciprocal inhibitory actions are normal phenomena, and serve to illustrate how easily micturition may be rendered difficult or impossible by the action of afferent impulses on the centres in the cord. Li Virghi, who is the chief exponent of the dynamic theory, has made use of these inhibition phenomena to explain the difficulty in micturition that is associated with an enlarged prostate. To him the enlarged prostate is the starting point of afferent impulses which produce reflex spasm of the internal sphincter. According to his view the retention produced by prostatic enlargement could be cured by any procedure that threw out of action the sphincter, even if it left the prostate *in statu quo*.

When we examine this spasm theory critically we find it difficult to accept as a complete explanation of the retention caused by prostatic enlargement. In the first place, the retention of hydronephrosis, with which we started, does not provide a true parallel to that which accompanies enlargement of the prostate. In the case of the kidney no mechanical explanation of the dilatation of the renal pelvis is available, whereas for the bladder we have a satisfactory theory of obstruction. Moreover, as Joly has pointed out, a persistent spasm of the bladder sphincter should lead to organic changes in that structure which have not been found to be present. The spasm theory is merely an attempt to provide an explanation of certain anomalies for which we have already obtained a satisfactory explanation along mechanical lines.

But although spasm cannot alone be responsible for the retention of prostatic enlargement, it may still be regarded as a contributory factor in its production. Everyone who has had under his care a patient showing signs of prostatic obstruction must have been struck by the wide variations that occur from time to time in the severity of the symptoms. Not only does the difficulty of micturition vary at different hours of the day, but it is subject to periods of improvement and aggravation. It is probable that the vascular state of the prostate accounts for some of these fluctuations, and that the increased difficulty that is usually noted on rising in the morning is due to congestion following long repose in the recumbent position; but it is unlikely that changes in vascularity are alone responsible for all the variations in the severity of the symptoms. A medical patient of mine told me recently that he had found that there existed a definite connexion between the hydrogen-ion concentration of his urine and the frequency and difficulty of his micturition. He found that he could obtain relief when suffering from increased frequency by taking large quantities of alkalis. In his opinion an acid tide was the cause of his nocturnal frequency, and in order to combat it he took 20 grains of sodium bicarbonate before retiring to rest. If his observations are correct, the most likely explanation of the phenomenon is that the more highly acid urine provoked a spasm of the sphincters. That spasm may be a factor in the causation of symptoms is also supported by the experience of some urologists that a temporary improvement in the micturition of a prostatic may be obtained by the instillation of cocaine or novocain into the posterior urethra. Warm baths may also act by relaxing spasm as well as by diminishing prostatic congestion. It is also possible that the amelioration in symptoms that sometimes follows the use of such treatment as diathermy applied through a rectal electrode, moderate doses of x rays, and high-frequency currents is the result of an action on the spasm rather than on the size of the prostate. Certainly in those cases that have come my way which have responded to these measures I have never been able to detect any alteration in the appearance or dimension of the prostate after treatment.

The most probable explanation of retention in cases of prostatic enlargement is therefore that there exists a constant mechanical factor in the enlargement of the prostate, a variable one in its state of vascularity, and a third variable neurogenetic factor in the tendency to spasm of the internal sphincter. With this working hypothesis in our minds we will now turn to the question of treatment.

Treatment.

The treatment of any disease, if it is to be rational, must be based on a clear appreciation of its pathology. It is for this reason, and because I have the impression that although prostatic surgery has made great progress during the last twenty years it runs the danger of becoming too stereotyped, that I have discussed at some length the mechanics and dynamics of retention. There is a tendency in some quarters to regard the fact that the gland is enlarged as the all-important point, and as a consequence its removal as the primary object of treatment. In my opinion this view of prostatic enlargement and its treatment is a narrow one, and I shall try to look at the subject from a slightly different angle.

A patient with commencing prostatic obstruction is not unlike one with mitral stenosis. The bladder, like the heart, responds to the obstruction by hypertrophy of its walls. For a time complete compensation may be maintained. There is always, however, the danger that a gradual dilatation may occur, or else that some accident may precipitate a complete breakdown in function. For this reason the patient who is suffering from mitral stenosis or prostatic obstruction must be put on a careful regime, and kept under constant medical supervision, so that the earliest signs of dilatation may be detected, and the accidents that are likely to aggravate his troubles guarded against as much as is possible. It is therefore dilatation of the bladder and embarrassment of the kidneys, rather than enlargement of the prostate, that should preoccupy the medical man who is called upon to look after a patient with an enlarged prostate.

Fortunately, the man with prostatic obstruction is in a better position than the sufferer from mitral stenosis, in that his lesion is amenable to surgery, and a failure to intervene when this is indicated is a fault in treatment even more disastrous than that of intervening when it is not strictly necessary. To some medical men the surgery of prostatic trouble is synonymous with the word "prostatectomy," for the success of that operation has so impressed us that we tend to regard it as the beginning and end of treatment. Now, although for a large number of our patients total removal of the obstructing gland is the best and possibly the only measure available, there are others who neither require, nor should be subjected to, this ordeal. It is therefore our duty to avoid the temptation to fall back on a stereotyped treatment and to sort out those cases which can only be cured by prostatectomy from those that are amenable to less drastic measures.

To furnish a complete catalogue of the types of prostate that may cause obstruction would be to expand this paper to impossible lengths. However, it will be a sufficient approximation to the truth if we divide obstructing prostates into six big groups, the first five of which are glandular in origin, and the last fibrous.

1. Cases showing considerable enlargement of the lateral lobes.
2. Cases in which there is a marked intravesical projection of the so-called middle lobe.
3. Cases that are a combination of 1 and 2.
4. Cases in which cystoscopy reveals an obstruction of the bladder neck by smaller masses that in all probability originate in the subcervical and subtrigonal mucous glands described by Albarran.
5. Malignant prostates.
6. Fibrous bar formations.

It is obvious that no standardized treatment can be meted out to such varied needs, and that, in the hackneyed words of the textbooks, each must be treated on its own merits. Of malignant prostates I intend to say nothing, except that the chief indication is to deal with the obstruction and to treat the growth by means of radium. For Classes 1 and 3, where the total enlargement is considerable, prostatectomy is usually indicated, since any other measure is likely to produce an effect that is temporary or incomplete. In Class 2 total prostatectomy may also be the operation of choice, but I have had cases in which a permanent cure has been obtained by removing only the enlarged middle lobe and leaving the rest of the prostate *in situ*. It will be remembered that, according to Joly's theory, it is the height of the closed portion of the intravesical projection that is the determining factor in causing obstruction. For this reason it is of great importance in such an operation to remove not only the free portion of the middle lobe that projects into the bladder but also a V-shaped segment at its base. If the projection is a large one this is best done by open operation, and in order that the V may be cut right down to the beginning of the urethra without causing haemorrhage, a cold cautery knife may be used with great advantage. If the projection is inconsiderable the whole operation may be done by means of a large electrode working through an operating cystourethroscope.

Cases belonging to Class 4, in which cystoscopy reveals the presence of glandular elevations on the posterior portion of the vesical outlet, are particularly suitable to perurethral methods. Perhaps there are no patients in the whole of genito-urinary practice that have been a greater puzzle to the surgeon who is not an expert in cystoscopy and urethroscopy than those belonging to Classes 4 and 6. They complain of all the symptoms that are usually associated with prostatic enlargement, and yet, when examined per rectum, no increase in the size of the gland can be detected. It was for this type of case that the French invented the term "prostatisme sans prostate", but the name is a bad one, for although rectal examination may reveal no enlargement, cystoscopy always shows changes at the vesical outlet. The region to which the cystoscopist must pay chief attention, if he is to find the clue to diagnosis, is the posterior half of the internal meatus. Normally, when viewed through a cystoscope the sphincteric margin presents a regular, slightly concave outline in its upper and lateral parts, but below, where it merges with the trigone, it lacks definition. In other words, the shape of the normal margin is that of a horseshoe stood up on its points. In the type of case we are considering the posterior portion of the margin (that which lies between the horseshoe points) instead of being concave is convex. This is due to the existence of a definite ridge which marks off the surface that slopes down into the urethra from that which merges with the trigone. This ridge is present whether it be glandular as in Class 4, or fibrous as in Class 6, and the steeper the slope down into the bladder the more likely is there to be difficulty in micturition. A differentiation between Classes 4 and 6 may be difficult, but in the fibrous type of "bar" the thickening of the posterior lip is smooth and uninterrupted, and the distance between it and the verumontanum diminished. Other points useful in differentiating fibrous from glandular bars are the frequency in the former of a history of old prostatitis, and the commencement of the trouble at an earlier age than is usual with prostatics. A urinary infection is frequently associated with it.

There can be no doubt about the importance of being able to recognize these cases of prostatic "bar." The surgeon who fails to diagnose them, and attempts by suprapubic operation to carry out an enucleation, finds that he has set himself an impossible task. After a vain struggle to find an enucleable layer he is finally compelled to dig the gland out piecemeal with scissors. And yet, if the condition is recognized before operation and suitable measures employed, the results of treatment are excellent. In the glandular type the ridge is best destroyed by diathermy, applied either through an operating cysto-urethroscope or else by means of the diathermy punch. In the fibrous type the same treatment may be used, but not infrequently the condition yields to such simple measures as dilatation of the bladder neck by means of bougies, instillations into the posterior urethra, and prostatic massage. In any case, whether dilatation or diathermy be used, the patient is saved all the distress of a major operation, and his sojourn in hospital is cut down from a month to a week.

An objection may be raised that although these cases of obstruction from minor forms of enlargement exist, they are so rare that total prostatectomy is the only operation that need be considered. In my experience this is not so, for on looking through my records I find that an increasing number of cases of prostatic obstruction are becoming amenable to perurethral methods of treatment. It is for this reason, and because of the excellence of the results obtainable at a minimum cost to the patient, that I have insisted that the treatment of prostatic obstruction has

become too stereotyped. A distrust of tinkering and a desire to be thorough is characteristic of British surgery, but the mortality rate of total prostatectomy is still too high to allow of our being content with our present position.

Another argument, in addition to that of "tinkering," has been urged against operations that do not entail the complete removal of the prostate—namely, that some 11 per cent. of seemingly innocent enlargements contain foci of malignancy. But this argument presupposes that prostatectomy eliminates the possibility of subsequent malignant disease, which it does not. Enucleation leaves behind sufficient prostatic tissue to allow of a recurrence of malignant disease, and although the risk may be diminished by the operation, it is never eliminated. Moreover, the increased danger of prostatectomy more than counterbalances any slight addition to the risk of malignant disease that a partial operation may have entailed.

Conclusions.

In the foregoing paper I have attempted to make a broad survey of the mechanism of prostatic obstruction and to pick out some of those points which have appeared to me to be of importance. I have tried to shew that whilst a dynamic theory may account for the retention of a hydronephrosis, spasm of the vesical sphincter is a contributory rather than a primary factor in the causation of a prostatic retention. The explanation of retention that I have found most satisfying is that there exists a constant mechanical obstruction acting along the lines suggested by Swift Joly which is supplemented by the variable factors of congestion and spasm.

In discussing treatment I have emphasized the importance of treating each type of prostate on its own merits, and have called attention to the value, in selected cases, of such operations as the removal of a middle lobe and of perurethral diathermy.

PUERPERAL SEPSIS.

AN INVESTIGATION REGARDING CONTAGION, AND THROAT CARRIERS OF THE STREPTOCOCCUS HAEMOLYTICUS.

BY

E. FARQUHAR MURRAY, M.D., F.R.C.S.,

ASSISTANT GYNAECOLOGIST, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

THE respective parts played in the production of puerperal sepsis by contagion and infection from throat carriers of haemolytic streptococci have been investigated at the Princess Mary Maternity Hospital, Newcastle-on-Tyne. Outbreaks of pyrexia and definite sepsis occurring from time to time among "clean" cases, caused much anxiety and demanded investigation.

In addition to its own booked cases, the hospital receives patients from a very large area, sent in by doctors on account of puerperal sepsis, difficulties arising during or immediately after labour, abortions, and so on. Many of these cases, when admitted, are "suspect" as regards infection, and many are frankly septic. The figures for 1929 were: puerperal sepsis, 108; "suspect," 302; abortions, 280. Patients requiring Caesarean section are not included, nor are those patients suffering from pyelitis and other medical conditions which were admitted during pregnancy from the ante-natal department, or sent in by doctors. Many of the "abortion" cases were septic or developed temperatures after admission.

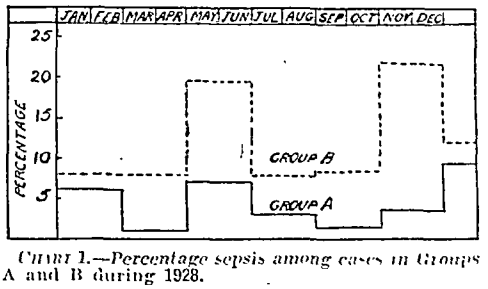

CHART 1.—*Percentage sepsis among cases in Groups A and B during 1928.*

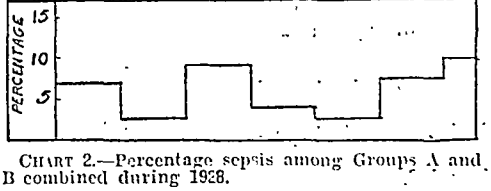

CHART 2.—Percentage sepsis among Groups A and B combined during 1928.

The existing system had certain obvious defects. (1) All cases, whether suspect or septic (except Caesarean sections) were delivered in the labour ward. (2) The isolation department, consisting of 9 beds, was unequal to the demand made upon it. In consequence septic cases occasionally, and suspect cases as a rule, were nursed in the general wards. Precautions were taken to isolate them as much as possible from the other patients.

The following changes were effected on May 1st, 1929. (1) A room was set apart where each patient, on admission, was examined and classified as "clean," "suspect," or "septic." (2) The operating theatre was converted into a labour ward for suspect and septic cases, the labour ward being reserved for clean cases only. (3) The isolation department was increased by 15 beds, making a total of 24, by including one of the general wards in that department. The isolation of suspect and septic cases, their nursing staff, baby room, and annexe, was complete. Improvement was noticed at once.

The terms "septic," "suspect," and "clean" must be clearly defined.

Septic.—This term is too limited in its application, for inflammation may be afebrile and extragenital; therefore such conditions as pyelitis, inflamed breasts, vaginal discharges, bronchitis, discharging sinuses, boils, and all patients admitted with high temperatures, must be regarded as infective.

Suspect.—This term is usually applied to patients admitted in labour who have been examined, or on whom attempts have been made to deliver with forceps before admission; it may be used too loosely. Many patients sent in by doctors have not been examined before admission and are not suspect. The responsibility for their safety rests with the hospital.

Clean.—These patients have no infective process, either local or general. The majority quoted in the results had been admitted from the ante-natal department, but a number had been sent in by doctors. They consist of two groups:

Group A patients are normal medically and obstetrically, and have had the routine vaginal examinations and possibly a forceps delivery or perineal repair.

Group B patients are handicapped by one of the following conditions:
Medical: Disease of the heart, lungs, kidneys, ductless glands.
Surgical: Loss of blood, antepartum or post-partum.
Obstetrical: Induction of labour, internal version, plugging, manual removal of placenta.
Anatomical: Slight degrees of pelvic contraction.

Group A cases are the most reliable, and Group B cases the most sensitive index of the efficiency of a hospital routine.

A study of cases which are already suspect or septic has very little value in such an investigation. The following standards were established before analysing the results.

1. Cases in Groups A and B were delivered in hospital after the twenty-eighth week of pregnancy, and, with only a few exceptions, at term.

2. Only notifiable temperatures were recorded—for example, 100.4° F., sustained for twenty-four hours, or occurring twice in twenty-four hours (excluding the day of delivery). Temperatures were recorded up to the twenty-first day if residence in hospital after the routine tenth day.

3. The [illegible] was made either by direct clinical evidence or by a process of exclusion; thus all temperatures not definitely diagnosed as due to some extragenital lesion were attributed to sepsis.

The accompanying charts show the incidence of septic temperatures for Groups A and B, independently and combined. The results are based on two-monthly records, the average number of cases in each record being as follows. In 1928: Group A, 167; Group B, 37. In 1929: Group A, 173; Group B, 36. The percentage sepsis among the two groups during 1928 is shown in Charts 1 and 2. On May

1st, 1929, the new routine was put into operation. This included, in addition to the foregoing, the immediate isolation of any hitherto "clean" case which showed the least evidence of temperature or genital or extragenital inflammatory process. The percentage sepsis for Groups A and B during 1929 is given in Charts 3 and 4. In Chart 5 is shown a comparison of Groups A and B combined

(*b*) Rigid isolation and intensive nursing of suspect and septic cases.

(*c*) Immediate isolation of any "clean" case which shows the least evidence of a genital or extragenital inflammatory process.

(*d*) Provision of a separate nursing staff for the extern department.

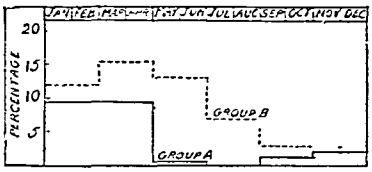

CHART 3.—Percentage sepsis among cases in Groups A and B during 1929.

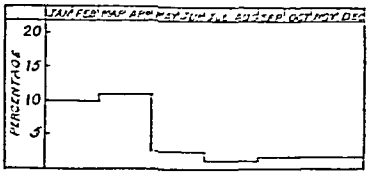

CHART 4.—Percentage sepsis among Groups A and B combined during 1929.

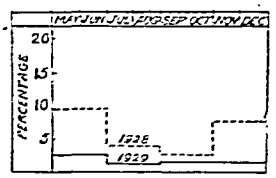

CHART 5.—Comparison of incidence of sepsis among Groups A and B combined during the periods May-December, 1928 and 1929.

for the periods May to December, 1928, and May to December, 1929.

The beneficial results can be given numerically as follows: for the periods May to December, 1928 (old routine), and May to December, 1929 (new routine).

	1928.		1929.	
	Total.	Sepsis.	Total.	Sepsis.
Group A cases	679	24 = 3.5%	657	6 = 0.9%
Group B cases	155	23 = 14.8%	135	7 = 5.2%
Group A and B combined ...	834	47 = 5.6%	792	13 = 1.6%

Suspect Cases.—It is obvious that "clean" cases benefit by being strictly isolated from suspect and septic cases; the latter two also benefit by getting more intensive supervision and nursing. This is proved by the observations recorded in Charts 6 and 7, which show the incidence of septic temperatures among the suspect cases. Analysis of a series of typical suspect cases, the majority being sent in by doctors, affords further proof of this contention. These included cases of accidental haemorrhage, placenta praevia, contracted pelvis, failed forceps, prolonged labour, and malpresentations. These showed improvement under the new routine as follows:

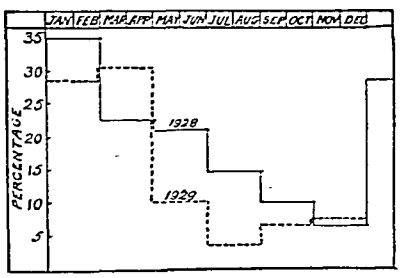

CHART 6.—Percentage sepsis among suspect cases during 1928 (continuous line) and 1929 (broken line).

	Total.	Sepsis.
May–December, 1928	209	26 = 12.4 %
May–December, 1929	204	14 = 6.9 %

It is interesting to note that a new routine was established in the extern department. Prior to July 1st, 1929, nurses, irrespective of their hospital duties, were called to attend district cases. From July 1st, 1929, a special district staff was organized, under the direction of a district sister. The results as regards notifiable pyrexias believed due to sepsis were:

	Total.	Sepsis.
July–August	113	4 cases.
September–October	114	1 case.
November–December	99	0 case.

Conclusions.

1. Outbreaks of pyrexia and sepsis in maternity hospital practice are due to contagion.

2. These can be prevented by (in addition to ante-natal care) the following:

(*a*) Examination and classification of cases on admission to hospital.

THROAT CARRIERS OF THE HAEMOLYTIC STREPTOCOCCUS.

The precautions regarding the prevention of contagion had been in force for two months when this second investigation was started. This was fortunate, since otherwise any observations made would have been most *misleading and inconclusive. From July 1st to October* 31st, 1929, some general observations were made which helped to decide the way in which the matter could be most effectively investigated.

1. Cultures were taken from the throats of residents, students, or nurses who had delivered "clean" cases. One nurse in the labour ward and two students were reported positive, and were at once suspended, although the nurse was allowed to do dressings, provided she wore a mask. A further series of positive reports on the indoor staff, and the fact that the entire outdoor staff were reported positive, made it clear that wholesale suspensions would entail either closing the hospital or seriously curtailing its work. It was also obvious that the wearing of masks by the district staff would produce alarm and arouse comment. It was therefore decided not to wear masks, but to take the following precautions: (*a*) all carriers were warned against coughing on their hands, instruments, dressings, or patients; (*b*) they gargled with boric lotion thrice daily, and their throats were painted once daily with 90 grains of resorcin in 1 ounce of glycerin.

2. The result of this treatment was fairly satisfactory. After five days treatment was suspended for two days, and a second culture was taken. If this was positive treatment was resumed, while if it was negative a confirmatory report was made after fourteen days. The second and third reports were usually negative; several, more resistant, were positive at the second report, had further treatment, and were negative at the third, while in two cases the reports were persistently positive, in spite of a continuance of treatment.

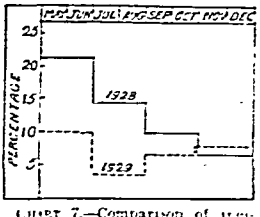

CHART 7.—Comparison of incidence of sepsis among suspect cases during the periods May-December, 1928 and 1929.

3. A patient developed a septic dermatitis on the buttocks. The student who delivered her was positive and had a bad throat. The nurse in attendance was also positive. Cultures taken from the pustules showed the presence of *non-haemolytic streptococci*. The patient's throat was negative, and she had no sign of genital sepsis. The student may have been the infecting agent, but the fact that the patient was an epileptic suggested other possible means of infection.

4. False deductions may be made unless every possible source of error is eliminated. A nurse (positive) was associated with a series of cases of non-notifiable temperature and mild genital sepsis. Certain of her colleagues who were interested in these observations indicated privately that it was not her throat but her careless technique which was responsible for the bad results.

5. One nurse, known to be positive, developed an acute throat, and the culture which was taken at that time was negative.

6. The possibility of attendance on septic cases being the means of infecting a nurse's throat was considered. Two nurses who had been in constant attendance in the isolation department for six months were negative, and the sister in charge, who entered the department positive, was after three and a half months' residence found to be negative. In neither instance was antiseptic treatment of the throat carried out.

7. These preliminary observations showed that throat carriers of haemolytic streptococci are extremely common, and that the organism in that locality is very susceptible to treatment and other hazards of its existence. This last is proved by a later observation, which showed that fifteen nurses reported positive in November were negative in January without any local treatment being used, while six nurses reported negative in October were positive in January.

The known prevalence of the organism, and the rarity and trivial nature of the temperatures which occurred among the clean cases following the established precautions regarding contagion, made it clear that a conclusive test must be made which would leave no vestige of doubt regarding the reputed danger of throat carriers to parturient women.

There were two weak links in the chain of evidence to date: (1) positive carriers had been submitted to an antiseptic throat routine; and (2) only those who delivered the patients had been examined—not the dressers.

To make the test conclusive it was necessary: (1) That all the nursing staff should be examined. (2) That all antiseptic treatment of the throat should be discontinued. (3) That only clean cases, Groups A and B, should be investigated. (4) That no masks should be worn.

The test lasted from November 1st to December 31st. The entire staff—doctors, students, and nurses—were examined. Of the 50 persons from whom swabs were taken, 34 (68 per cent.) were positive.

A record was kept of the work done by each person reported to be positive. This was easy as regards deliveries, but it was a little difficult to keep a complete list of all dressings done by the nurses. The officially recorded number of patients dressed by "carriers" is certainly an underestimate.

Clean cases were delivered or dressed by "carriers" as follows:

Deliveries.—Hospital: total deliveries 183; by carriers 102. District: total deliveries 99; by carriers 47. The district sister-midwife (positive) assisted at nineteen of these deliveries, while the district medical officer (positive) delivered with forceps, or repaired lacerations, on twenty-six occasions.

Dressings.—Hospital and district 478. This number represents individual patients dressed by carriers, but as only 282 patients are under review, it will be clear that a number of patients were dressed by more than one carrier.

Results—Indoor.

Chart 4 shows that the incidence of sepsis in hospital during November and December was the same as during the previous four months. The detailed statistics are as follows:

	Sepsis.
Group A cases:	
September–October, 1929	1.1 %
November–December ,, ...	2.1 %
Group B cases:	
September–October, 1929	2.8 %
November–December ,, ...	nil
Combined Groups A and B:	
September–October, 1929	1.4 %
November–December ,, ...	1.6 %

The three cases of sepsis among the 183 clean cases delivered in hospital were analysed. All three were trifling, and the temperatures were notifiable on 1, 1, and 2 days respectively.

Case 1.—One day's pyrexia. Delivered by a positive and dressed by negative.

Case 2.—One day's pyrexia. Delivered by a negative and dressed by two positives.

Case 3.—Two days' pyrexia. Delivered by a negative; dressed by two negatives.

Throat and vaginal cultures were taken from the patients in Cases 1 and 3. It is significant that all were negative except the vaginal culture in Case 3, which was positive.

The total district deliveries for September–October, 1929, numbered 114: sepsis 0.8 per cent. The total for November–December was 99: sepsis *nil*.

It will be seen that the excellent record resulting from the precautions regarding contagion was not in any way affected by this exposure to *presumed gross potential infection*.

The suspect department afforded a certain amount of material for this investigation. During November and December 19 suspect cases were delivered by carriers and showed no ill effects.

Conclusions.

It is possible that an individual with an acutely septic throat may cause puerperal sepsis by coughing on his or her hands, dressings, instruments, or patients. Any attempt to obtain positive proof of this would be on a par with observations regarding the results of vaginal examinations made with fingers suffering from whitlows, or of surgeons with septic throats coughing into abdomens at laparotomies.

The sum total of the combined investigations indicate:

1. That outbreaks of fever or definite sepsis in maternity hospital practice are due to contagion, and are preventable.

2. That throat carriers of the *Streptococcus haemolyticus* are very prevalent, and that apart from a negation of surgical and aesthetic principles—for example, coughing on hands, instruments, dressings, or patients—they are *not* a danger to parturient women.

In carrying out these observations special thanks are due to the matron, Miss Ferlie, and her nursing staff, and to Drs. Ind, Cover, and Blaiklock for their valuable and most willing assistance.

THE MECHANISM OF REFERRED PAIN IN DYSPEPSIA:

*ITS REFLECTION ON THE RESPIRATORY AND CIRCULATORY SYSTEMS.**

BY

A. T. TODD, M.B.Ed., M.R.C.P.Lond.,

HONORARY ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY.

THE term "dyspepsia" is here employed literally to mean a group of symptoms associated with abnormal digestion produced by any cause. Pain is a symptom in many cases, by no means in all. Though the cause of the dyspepsia may vary within rather wide limits the pains tend to conform to a few types or mixtures of types. It is well known that the pains of ulcer, inflammation, or ulcerated cancer may strongly resemble each other; as a result the nature of the pain and its site have little or no value in differential diagnosis. The timing of the pain, too, is of limited significance, early and late pain being regarded as due to a higher and lower lesion respectively. This similarity of pain brought about by so very different lesions raises the thought that the nature of gastric pain is not understood.

There has been controversy on the mechanism of gastric and other visceral pain for many years; several theories have been advanced, but no single one has met with general acceptance. This article describes a modification of the theory propounded by the late Sir *James Mackenzie*.[1] The observations on which it is based have extended over some years, and their accuracy is proved by the finding that the signs can be predicted from the symptoms.

The current theories to explain pain in gastric disease fall under two main heads:

1. *That the pain is felt in the affected viscus.* This is the popular theory; physician and patient speak of a pain in the stomach. The pain is regarded as being due to: (*a*) the action of hydrochloric or other acid on a sensitive mucosa or exposed submucosa; (*b*) abnormal contraction of the smooth muscle of the wall of the viscus; (*c*) stretching of the sensory nerves in the wall of the viscus; (*d*) stretching of the nerves or muscles of the supporting structures. There is abundant clinical and experimental evidence for each of these being a factor.

2. *That the pain is not felt in the viscus but is referred to some other structure.* It is of interest to us that one of the earlier propounders of this theory was a professor of physiology at the Bristol Medical School,[2] but his views were never widely known. The main upholders of this theory were Mackenzie and Head. Mackenzie considered that stimuli passed from the stomach via the lower dorsal sympathetic fibres to the corresponding spinal segments;

*The substance of a lecture delivered to the January meeting of the Bristol Medico-Chirurgical Society.

these segments became irritable after a time and then picked up normally subliminal stimuli, which were referred to the periphery as ordinary painful sensations. Most of us have experienced a demonstration of this theory—the throbbing of a septic finger or tooth socket. The subliminal sensation of the neighbouring pulsating arteries becomes perceived as a painful throb so long as the corresponding spinal segment is kept on the *qui vive* by irritation of the sensory nerves in and around the septic focus.

Mackenzie described areas of cutaneous hyperaesthesia related segmentally to the various viscera. In the case of the stomach he states that the segments affected are the lower dorsal. He refers also to muscular hyperalgesia, but is vague as to its site, and is content to call it epigastric. It was found that the systematic investigation of cutaneous hyperaesthesia was not of great help in the diagnosis of gastric conditions. On concentrating on the hyperalgesic muscles it was found that the cases fitted into patterns—certain groups of muscles were repeatedly found to be hyperalgesic. It is considered that these muscles are frequently spasmodically contracted, because the tension of the muscle is greater than that found in a relaxed normal, and greater than that of the other side of the body when pain is unilateral. At times, especially in the intercostal muscles, which lend themselves to this observation, it can be seen that the muscle is shorter than that of the unaffected side. It is granted that proof of spasm is not always complete.

It was soon seen that the muscles which became hyperalgesic were those classed under the muscles of respiration; in dyspeptics complaining of pain a section of the respiratory musculature has consistently been found to be hyperalgesic and often spasmodically contracted. The most frequently affected muscles are the abdominal recti and obliques, the anterior scaleni, the interchondrals, the lower intercostals, the triangularis sterni, and the diaphragm. In cases of dyspepsia showing present or recent pain some, or all, of these muscles have been found to be hyperalgesic, and pressure upon them has produced more or less severe pain; it is often found that pressure on one or more of them will reproduce the pain for which the patient seeks advice. This finding appears to be significant, for if pressure upon a fifth left interchondral or triangularis sterni reproduces the pain felt after food, it is unnecessary to throw the blame directly upon abnormal acidity or peristalsis.

Further support emerges from the examination of the dyspeptics who do not complain of pain. The common type labelled "hepatic" shows flatulence; feeling of weight and vague distress after food; inability to eat some or all fats, milk included; often inability to eat potatoes, however they are cooked; often showing a small or absent liver dullness and telangiectases about the diaphragmatic origin. This type seldom experiences pain of any severity, and muscular hyperalgesia is little marked or absent. Thus, when pain is present hyperalgesia, with or without spasm, of some of the respiratory muscles is found. Pressure on these muscles will frequently elicit the pain when absent and intensify it when present. When pain is not a symptom of any importance no hyperalgesia is found. The deduction follows that gastric pain is referred to some of the respiratory muscles, and that the visceral sensation of the stomach is perceived as weight or vague discomfort.

The findings are derived mainly from inspection and palpation. Instrumental demonstration is not necessary. The suspected muscles are gently palpated, and, if found to be hyperalgesic, the tone is compared with a similar muscle free from pain. The diaphragm cannot be palpated. Evidence of diaphragmatic involvement is obtained from the amount of diminution of air entry at the bases of the lungs, measurement of the expansion of the lower thorax, degree of phrenic trunk tenderness (nerve palpated by pressing directly backwards between the two heads of the sterno-mastoid muscles), and direct observation with the fluorescent screen. The anterior scaleni are palpated against the transverse processes of the cervical vertebrae by dipping behind the sterno-mastoids. The triangulares are reached by hooking the finger upwards and outwards in the angles between the xiphisternum and chondral margins

The value of the hyperalgesia of the individual muscles or groups of muscles in the diagnosis of the site of the lesion is not great. In oesophageal and gastric disease the left side is more affected; in duodenal and gall-bladder disease the right side. Usually both sets are involved, but one side predominates, and this would be expected, for strict localization of lesions to one viscus is rare in the patient though common in the textbooks.

The exact cause of this reflection of gastric pain upon the respiratory musculature cannot be given with any certainty. There is no direct path over which a reflex like that of a tendon reflex could pass. An indirect path is known via the sympathetic nerves to the dorsal segments. We may accept Mackenzie's hypothesis of segmental irritability due to bombardment by impulses carried by the rami communicantes. Assistance from animal experimentation is not likely to be of very great help in demonstrating such a reflex path, for the animals do not use their thoracic respiratory muscles so much as man does—thus, one can straddle the thorax of a winded horse without much discomfort.

Another explanation becomes possible when the actions of the individual muscles are reviewed. It is generally accepted that disease of the abdominal viscera is usually accompanied by a protective immobilization, or spasm, of the overlying muscles; this is regarded as an attempt to rest or shield the part. Such a defence would involve the rectus and oblique muscles in disease of the upper abdominal viscera. Immobilization of these would diminish abdominal respiration, and, more important, would occasion a drawing down and fixation of the thorax. The thoracic respiratory muscles would have to labour against this load, the more so because of the diminution of abdominal respiration. It may readily be understood that these muscles might become fatigued and show the pain and spasm of fatigued muscles. A closer review of the muscles most affected shows that these muscles are regarded as having double function—they are inspiratory and expiratory. This appears to be significant; granted the overwork, then the muscles which work double time become the most fatigued. It is too early, and anyhow foolish, to be dogmatic in pressing this theory of muscular ill-balance: it is my impression that the severity of thoracic muscular hyperalgesia is proportional to the degree of defence in the upper abdomen.

The significance of this involvement of the respiratory musculature was not grasped for some years, but when one adds to the clinical findings the results of certain experiments, it appears astonishing that disorders of respiration are not even more frequent than is claimed. Thus, distension of the stomach, or a painful stimulus such as cold, occasions prolonged elevation and diminished expansion of the diaphragm[3]—perhaps the most important respiratory muscle. A stimulus to the stomach produces an expansion of the left side of the chest with eversion of the lower ribs; this impedes the action of the diaphragm,[4] and is perhaps a partial explanation of the left-sided preponderance of hyperalgesia in gastric disease. Increased intra-abdominal pressure, from gas or fluid, puts the diaphragm under stretch and diminishes thoracic expansion.[5] It would appear that any interference with the stomach will result in widespread upset of the respiratory muscles.

It is therefore not surprising that dyspeptics suffer from respiratory disorders, but it is rather surprising that complaint of such disorder is relatively uncommon. Shortness of breath is not often volunteered, possibly because the dyspeptic is frequently underfed, and does not engage in any work entailing exertion; the clerk will work for months with dyspepsia, but the labourer will give up in a week or so. Some do complain of shortness of breath, and occasionally it is the most noticeable symptom. A majority, when questioned, state that shortness of breath is present, and a large proportion of the cases state that exertion, as well as food, intensifies the pain. One can readily convince oneself of the frequency of shortness of breath in dyspepsia by timing the duration of voluntary apnoea; after a few deep breaths the patient is instructed to take as large an inspiration as possible and retain it as long as he can. Voluntary apnoea lasts about sixty seconds in the average healthy adult, but longer times are

acquired by training. *In painful* dyspepsia periods of five to twenty seconds are usually found. In a small proportion of the cases the respiratory symptoms so overshadow the other symptoms that cardiac disease is suspected by patient and physician.

It is well known that the dyspeptic often thinks himself to be suffering from disease of the heart. How often do we find ourselves saying: "That is not your heart, but your stomach"? It is sometimes noted that the patient is still sceptical, especially if he is a physician or has a smattering of medicine derived from the lay manuals. He feels a pain where he knows his heart to be (due to left triangularis or fifth left interchondral), he is short of breath on exertion, he often experiences disordered action of the heart or palpitation, and sometimes has distinct syncopal attacks. Is he to blame for suspecting his heart to be wrong?

On careful consideration the patient is in the right. The cardiologists have thrown the blame of heart disease on every part of the heart and vessels, but have, so far, failed to remember that the heart and vessels—the circulatory system of the present day—are but a half of the vascular pump. The heart and vessels can pump blood onwards efficiently if healthy and if blood is supplied to them, but the heart, by itself, cannot get blood to pump. The auxiliary pump is the respiratory musculature, which derives, or sucks, blood from the great venous cisterns to the right auricle. When the respiratory pump is thrown out of action the heart will stop, unless the body is in the horizontal position, for then respiratory suction is not necessary. The climber who falls on the rope soon succumbs to syncope, as the rope throws the respiratory pump out of action; the laboratory rabbit suspended in a vertical position dies of syncope in a few minutes, for the weight of its abdominal viscera and the poor tone of its abdominal respiratory muscles prevent respiration. It was noted above that the lower animals have little or no thoracic respiration.

We have seen that the dyspeptic frequently shows respiratory disability; he does not use his abdominal muscles because they increase his distress; he cannot use his thoracic muscles because they are painful. He has two causes for shortness of breath—his respiratory movements are inadequate to aerate his blood, and his respiratory pump fails to supply the heart properly with blood.

Another reflection of this referred pain in dyspepsia is seen in the cases which show anginoid pain, or pain which must be regarded as *identical with angina pectoris*. Such cases are not uncommon. Numerous observers have described the dyspeptic symptoms of angina, but few the anginal symptoms of dyspepsia.

The explanation of the syndrome angina has produced as big a literature as dyspepsia, for though not so common it is much more spectacular. Time forbids a long excursion into the various theories of its causation; in brief they are: disease of the proximal part of the aorta with pain radiating into the upper dorsal segments; disease of the coronaries with anoxaemic cramp of the myocardium; Briscoe's conception of fatigue of the respiratory muscles owing to a change over from youthful thoracic to elderly abdominal respiration; vaguer nervous mechanisms. Evidence for and against all these theories is abundant. It is not my object to deny that each or all of these may not be causes of anginal pain, but to point out the possibility that *these lesions may also result from the cause which* produced anginal pain.

When we consider the limitation of effort; the pain when effort is not limited; the immobility of the whole of the respiratory musculature, perceived as a sensation of a vice-like grip; the pallor and breathlessness; the absence of evidence of circulatory failure in the early stages; the dyspeptic symptoms—we have enough evidence to constitute a case for the dyspeptic etiology of angina, at least in some cases. In dyspepsia one can select a perfect sequence of cases to show all steps upward from simple pain after food, through the effort syndrome, to true anginal pain. The group showing this pain have recovered, up to the present, when the condition has been treated as a failure of the respiratory pump due to dyspepsia. It is admitted that the number showing severe pain of this kind is few, but a large number have shown milder degrees. The importance of the vascular lesions is not denied, and it may well be found that after a time the vascular lesion may become the chief one; it is contended that the vascular lesion may be produced by the angina. Proof for this contention is not complete, but there is some evidence; Cunliffe Shaw, Manouélian, Stopford, and H. Todd[6] have shown that prolonged irritation of the nerves of a part is followed by vascular degeneration in the territory supplied by these nerves. Is it not possible that the prolonged irritation of the sympathetic fibres proceeding from the abdominal viscera, and the sensory nerves supplying the hyperalgesic muscles, may cause vascular degeneration in the areas supplied by these nerves? It appears suggestive that the segments postulated to be concerned in gastric pain by Mackenzie are the same as those which are blamed by the upholders of some of the neurogenic theories of angina.[6]

It should be noted that hyperalgesia of the muscles of respiration is not limited to patients who suffer from painful dyspepsia. Similar hyperalgesia is found in subjects suffering from fatigue of respiration from purely respiratory and circulatory causes.

Summary.

1. Pain of some of the upper abdominal viscera is shown to be referred to some of the muscles of respiration.
2. This respiratory muscular hyperalgesia may interfere with the respiratory pump and the supply of blood to the right auricle.
3. It is considered possible that some cases of pain resembling angina pectoris are due to this factor, and that properly directed treatment may result in cure in the early stages.

CHRONIC HYPOGLYCAEMIA.

BY
P. J. CAMMIDGE, M.D.,
LONDON.

CHRONIC HYPOGLYCAEMIA is regarded by most clinicians as a rare phenomenon of scientific rather than of practical importance, but, as I have met with a fasting blood sugar of 70 mg. per cent., or less, in more than 200 patients during the past five years, it cannot be so uncommon as is generally assumed. Unfortunately there is no characteristic sign to draw attention to hypoglycaemia, as glycosuria does to hyperglycaemia, but in most cases the history and symptoms are sufficient to suggest a diagnosis if the possibility of its presence is borne in mind. It will, I hope, help others to recognize chronic hypoglycaemia more frequently if I classify and discuss my cases, most of which had been treated for a variety of symptoms without success until the abnormal condition of their blood was discovered.

AGE AND SEX.

The age of my patients ranged from under 1 year to over 70. Classified in decades (Table I), the highest proportion falls within the first ten years; in the next ten years there is a striking diminution, but in the following period the incidence increases again and is maintained at a fairly constant level up to the age of 50. Every age period, excepting 31 to 40, shows an excess of males, and the whole series gives a ratio between the sexes of about two to one. It is therefore clear that chronic hypoglycaemia is not limited to any particular age or sex, and that, although a low blood sugar figure appears to be most commonly associated with symptoms calling for treatment in children, no period of life is exempt.

HEREDITY.

Breeding experiments with mice, which Mr. Howard and I have been engaged upon for some years, have indicated that a naturally occurring hypoglycaemia is a hereditary character transmitted in accordance with Mendel's theory. It is interesting, therefore, to find that in my series of cases a history of symptoms suggesting a hypoglycaemic complex was obtained among blood relations in 35 per cent. The proportion of cases giving such a history was highest in the first ten years and steadily diminished with advancing age, falling from 70 per cent. in the first decade to 5 per cent. in the seventh. Such a distribution suggests either that the family history of parents is more reliable than adults give of themselves, or that heredity plays a greater part in the hypoglycaemia of early life than of later years.

Evidence of the transmission of a chemical abnormality is naturally more difficult to obtain in human beings than in animals, but in 48 of my cases of chronic hypoglycaemia, distributed in nineteen families, experimental proof has been possible. A low blood sugar figure was found in one of the parents of affected children in 36 instances, two patients were uncle and nephew, cousins were similarly affected in two families, and a daughter, mother, and grandmother in another. The last is particularly interesting, as it indicates that, given suitable conditions, the abnormality may appear in at least three successive generations.

CHRONIC INFECTION AS A CAUSE.

Although animal experiments and human histories both suggest that heredity is a predisposing cause of chronic hypoglycaemia, it is probable that an exciting agent is necessary for the development of the condition as a rule, and maybe is the sole cause in some cases. In my experience the most common exciting cause is a chronic infection, which, in the early years of life, is often located in the tonsils, antrum, or middle ear, and later in life is often met with in the mouth, but at all ages is most frequently found in the intestine. Comparatively few patients with chronic hypoglycaemia are free from gastro-intestinal disorders; long-standing constipation is common, but frequent and offensive stools are not unusual, especially in children, and some patients have distension, flatulency, and heartburn. Even when no complaint is made, examination of the faeces very commonly reveals abnormalities of digestion and absorption. The analyses in my cases have pointed to a chronic intestinal catarrh involving both the large and small intestine in over 47 per cent.; in another 24 per cent. the upper intestinal tract was mainly affected, and in 16 per cent. the large bowel was chiefly concerned. Experiments upon animals have demonstrated that the injection of a poison having a specific action on the liver, such as hydrazine phosphate, is followed by a fall in the blood sugar level,[1] and it is possible that chronic infection may act similarly as an exciting cause of hypoglycaemia by interfering with the functions of a liver already more or less inefficient congenitally. Further, since a chronic catarrh of the upper intestine is generally associated with an infection of the bile and pancreatic ducts, the consequent disturbances of the functions of the liver and pancreas may contribute to the production of a low blood sugar in that type of case. Whatever the explanation may be, I find that patients with chronic hypoglycaemia and intestinal disturbances do not improve satisfactorily unless the bowel condition is successfully treated.

THE URINE.

At first sight it is rather strange that sugar should have been found in the urine of 53 per cent. of my cases, in spite of the fact that the blood sugar level was invariably subnormal and never attained a percentage at which glycosuria might be expected. In 19 cases the sugar proved to be pentose, laevulose, pseudo-laevulose, or lactose, but in the majority it was found to be entirely, or almost entirely, dextrose, thus indicating abnormal permeability of the kidneys for that sugar. The low renal threshold for glucose was possibly accounted for in some instances by a low calcium content of the blood[2] produced by an excessive loss of lime through the walls of the large intestine,[3] or by way of the kidneys; but as dextrose was discovered in the urine of 18 patients whose blood calcium proved to be within the normal range, a deficiency of lime salts was evidently not the only explanation. In 46 cases where the urine was found free from sugar, the presence of an excess of dextrins pointed to there being defects of carbohydrate metabolism due to faults in the functions of the liver or pancreas.

Albumin was rarely encountered in the urine, only 13 per cent. showing traces; these traces could usually be accounted for by an associated oxaluria, probably produced by abnormal fermentative changes in the contents of the upper intestine.[4] When I first drew attention to the chemical abnormalities occurring in children suffering from cyclical vomiting, in 1923,[5] I pointed out that the alkali reserve is apt to be reduced and that acetone is very frequently present in the urine. Subsequent experience has confirmed these observations, and also shown that acetonuria is not uncommon in other conditions where chronic hypoglycaemia is a feature. Acetone was discovered in the urine of 29 per cent. of the cases in the present series, and it is worthy of note that it occurred with diminishing frequency as the ages of the patients increased, falling from 65 per cent. in the first decade to 6 per cent. in the seventh. Sugar was found in the urine with the acetone in 74 per cent. of the cases, and when acetone was present alone the patients were usually children. The cause of the acetonuria is no doubt essentially the same as in chronic hyperglycaemia, although the mechanism of its production is different. In both the acetone arises from defective oxidation of fat owing to a deficiency of available sugar, but in hyperglycaemia the deficiency is due to inability of the tissues to use the abundance of sugar present in the circulation, whereas in hypoglycaemia the supply in the blood is insufficient, the power of the tissues to store and utilize sugar being normal.

SYMPTOMS.

The cases with a low blood sugar coming under my care fall into two main groups: (1) those where the hypoglycaemia was definitely part of a symptom complex of which complaint was made (128 patients); and (2) those where the condition of the blood was discovered incidentally in the course of examinations for some other purpose (72 patients). The character of the symptoms in the first group varied considerably, and, while some apparently resulted directly from the low sugar content of the blood, others were more probably attributable to the effect of fundamental pathological changes, of which the hypoglycaemia itself was an expression. The distinction is, however, of theoretical rather than of practical importance for treatment bringing about a permanent rise in the blood sugar has been found to ameliorate the symptoms in either case. This group can be best considered in sub-divisions corresponding to the prevailing clinical features.

Cyclical Vomiting of Children.—The more important results obtained in the investigation of 32 cases of this type are summarized in Table II. These confirm the conclusions I reached nearly seven years ago, but I may draw attention to a few points of particular interest. The most important is the evidence these figures furnish of the hereditary nature of the condition, there being in 73 per cent. of the cases a history of similar symptoms occurring in a blood relation, but not necessarily in an immediate relative. The percentage of cases (55) with evidence of a chronic infection is also striking, but even more remarkable is the very high percentage (84) which, on analysis of

TABLE II.

Symptom.	No.	Age Incidence.	Sex.		Heredity.	Chronic Infection.	Faeces.				Urine.				Blood.

the stools, were found to be suffering from chronic catarrh of the intestinal tract. Early prophylactic treatment for the children of hypoglycaemic parents and recognition of the part chronic infection and toxic absorption play in the production of cyclical vomiting are, I believe, the essentials for success in dealing with a very troublesome complaint.

Recurrent Bilious Attacks.—Sporadic "bilious attacks," usually precipitated by indiscretions of diet, are too well known to call for comment, but the severe recurrent attacks, coming on at short intervals and incapacitating the subject for a day or two, of which the 13 patients comprising this group complained, are a very different matter. All the patients were beyond the age when cyclical vomiting occurs, but in several instances there was a history of attacks in childhood, and a family history of vomiting or of bilious attacks in 46 per cent. Evidence of chronic infection, apart from the intestine, was much less common than in the preceding group, but analysis of the faeces revealed a possible source of toxaemia in the alimentary tract in every case. Nine of the 13 patients passed sugar in their urine, but further examination showed that this consisted mainly of laevulose, pseudo-laevulose, or pentose in 7. Acetone was discovered in the urine of 5 cases (38 per cent.), a much smaller proportion than was found in the children suffering from cyclical vomiting (94 per cent.).

Pernicious Vomiting of Pregnancy.—Four of the 6 patients in this group were sent to me after labour had been induced, as the persistent presence of sugar and acetone suggested they were suffering from diabetes, but the discovery of a subnormal blood sugar disproved the diagnosis. In 2 the glycosuria was probably accounted for by a low percentage of calcium in the blood, and in the other 2 the sugar proved to be a mixture of laevulose and lactose, with a very slight excess of glucose. The remaining patients came with intractable vomiting, both had low blood sugars, and both were excreting acetone in their urine, but neither was passing any sugar. Three patients gave a family history of a hypoglycaemic complex; 4 had children who suffered from cyclical vomiting and were proved to have low blood sugar figures. Evidence of an abnormal condition of the intestinal tract was found in all the cases.

In spite of differences, possibly attributable to the ages of the patients and the character of the diet, the recurrent bilious attacks of adults, the pernicious vomiting of pregnant women, and the cyclical vomiting of children, have so many points in common that it would seem probable their etiology and pathology are similar, if not identical. The fundamental defect is almost certainly in the liver, and, in most cases at least, is inherited. Occasionally it is so severe as to cause symptoms at an early age, but, as a rule, it is only brought into prominence at a later stage by the cumulative effects of an acquired infection, an unsuitable diet, or a growing foetus which overstrains the defective hepatic functions. Hypoglycaemia, although a constant feature and undoubtedly the cause of the acetonuria in some instances, is mainly important as an index of the severity of the liver deficiency to which it is related.

Recurrent Headaches.—The cases falling in this category are of two types—one where the attack recurred at intervals measured by days or weeks, the other where the headache, which was of a less severe character, was of daily occurrence and was particularly prominent in the morning or after an unusual strain. The former is probably akin in origin to a recurrent bilious attack, the latter appears to be a direct effect of the low sugar content of the blood, and can be prevented by a light meal or a dose of glucose, in the morning before rising. Both varieties were met with at all ages between 12 and 50, but a morning headache was more common in middle life. A hereditary basis appeared to be present in 35 per cent. of the cases; a chronic infection was discovered in 46 per cent., and 87 per cent. were shown by analysis to have affections of the intestinal tract. Thirteen patients excreted sugar in their urine, and 5 acetone as well. The urine of 6 contained an excess of calcium, and all but one of these were found to have oxaluria and to be passing traces of albumin.

Neurasthenia was the diagnosis with which 11 patients, subsequently found to have a low blood sugar, came to me, but as they rapidly improved when the hypoglycaemia was treated, and the intestinal disturbances from which they all suffered were corrected, it appears probable that their symptoms were connected with the deficiency of sugar in their blood. A family history suggesting a hypoglycaemic complex was obtained in only 27 per cent. of the cases in this group, and no exciting cause in the form of a chronic infection was discovered in any. On the other hand, the proportion (64 per cent.) suffering from chronic catarrh of the whole intestinal tract was remarkably high.

Convulsive Attacks.—Four of the cases coming under this heading were believed to be suffering from mild epilepsy; 2 had been diagnosed as having Ménière's disease, and one was reported to be a victim of secret alcoholic excess, although he was actually a total abstainer. The attacks of inco-ordination of movement from which they suffered were proved to be associated in every instance with a pronounced hypoglycaemia, and were prevented by raising the sugar content of the blood artificially. There can be little doubt, consequently, that there was a direct connexion between the symptoms and the low blood sugar level. The attacks developed rather late in life in all the cases, the youngest being 40 and the oldest 72 years of age. No family history bearing on the condition could be obtained from any of the patients, but all were found to be suffering from abnormalities of digestion and absorption, which may have been the exciting cause of the hypoglycaemia.

Lack of Energy.—Mild hypoglycaemia does not give rise to noteworthy symptoms unless there is some complication; if the patient complains at all, he usually says he lacks energy and is very easily tired. On inquiry, it is often discovered that consecutive thought is difficult, and work requiring concentration can only be performed with great effort. As a rule, the symptoms are most pronounced in the morning and diminish as the day advances, especially if small frequent meals are taken, as many patients have learnt from experience. Most of the 33 patients with hypoglycaemia of this type seen during the past five years were sent to me as diabetics, owing to their lack of energy and the discovery of sugar in their urine. A smaller number came on account of digestive troubles, which were held responsible for their lassitude, but, although that may have been a partial explanation in some instances, the history of many, and the response of all to symptomatic treatment for hypglycaemia, indicated the low blood sugar as the more important factor. As a whole the group contained a high proportion (75 per cent.) of cases exhibiting evidence of affections of the upper intestine, and comparatively few (6 per cent.) were found to have normal faeces. A hereditary factor in the production of the hypoglycaemia was suggested by the histories of 23 per cent.

Life Insurance.—A previous application for life insurance is usually presumptive evidence that the applicant considers his health is normal, and this was so with the 24 patients we are now considering who had been rejected on medical grounds. Careful inquiry disclosed, however, that most of them had experienced symptoms which could be reasonably attributed to a deficiency of sugar in the blood, and in some instances these symptoms dated back to early childhood. Twenty-two of the cases had been rejected by the insurance examiners for glycosuria and two for albuminuria. Blood examinations showed no evidence of renal disease in either of the latter, and the albuminuria was probably of the "cyclical" type. The glycosuria in the other cases was evidently dependent upon a low renal threshold for glucose, which was associated with a subnormal percentage of calcium in the blood in 9. The presence of traces of acetone in the urine of 3 patients indicated defects of fat and carbohydrate metabolism. Evidence of heredity was obtained in 37 per cent. of the cases. Analysis of the stools gave normal results in slightly over 25 per cent.—a higher proportion than in any other group.

Routine Examination.—Routine examination of the blood revealed 48 cases of chronic hypoglycaemia; the majority were sent to me for the elucidation of obscure disturbances of digestion or metabolism, but 6 came for treatment for obesity, 4 had gall-bladder affections, 2 were suffering from pernicious anaemia, one was found to have cancer of the pancreas, and a child was examined on account of delayed development. Evidence of heredity as a causative factor of the hypoglycaemia was found in only 15 per cent. of this group, and the positive cases were nearly all children. Chronic infection as a possible exciting cause was present in 52 per cent., and affections of the intestinal tract in 86 per cent. One-third of the patients passed sugar in their urine, but this was associated with acetone in only one instance. Albumin was found in the urine in 29 per cent.—a higher proportion than in any other group, which is possibly accounted for by the relatively large proportion discovered to be excreting an excess of calcium in the form of oxalate crystals.

The case of cancer of the pancreas mentioned in the last group is of interest since it is one of the few in which conclusive evidence was obtained that the hypoglycaemia was entirely dependent upon an abnormality of the pancreas. Theoretically hypoglycaemia may arise in two ways: either from an inadequate supply of sugar to the blood by the liver, or from an abnormal removal of sugar from the circulation consequent upon excessive formation of the pancreatic internal secretion, but it is not easy to distinguish in practice. A differential diagnosis is sometimes possible from the clinical characters of the case, for hyperinsulism is usually characterized by a comparatively rapid onset and progressively increasing faintness or severe hunger between meals; it is promptly relieved by food, and occurs in a previously healthy person, who is practically always an adult. Hypoglycaemia due to hepatic defects is, however, common in children as well as in adults; it is generally associated with a more gradual onset, less definitely related to meals, and of a milder and more chronic character, which may be connected with an infection or other exciting cause, and may be hereditary. As a rule, a reliable diagnosis can only be made if the results of analyses of the blood and excreta are taken into account. The character of the symptoms, and the analyses made in my cases, have suggested a hepatic origin for the hypoglycaemia in the majority; hyperinsulism appeared to be an additional factor in some where there was an infection of the upper intestine, and in only a small proportion could the low blood sugar be attributed entirely to an excessive formation of insulin by the pancreas.

Whether a chronic hypoglycaemia gives rise to symptoms demanding treatment or not depends largely upon the manner of its production and the conditions associated with it. I have met with patients whose blood sugar frequently dropped as low as 40 mg. per cent., yet they appeared to be healthy; on the other hand, patients with appreciably higher blood sugar figures suffered from symptoms which seriously interfered with their comfort or occupations. The explanation of the difference seems to be that in the latter the hypoglycaemia had developed comparatively suddenly, possibly as the result of some intercurrent infection which, besides depriving the tissues of their accustomed supply of sugar, affected them in other ways; whereas the former had been used to a low blood sugar all their lives, since their history pointed to the existence of the disability from early childhood, and there was in most cases a family history as well. A congenitally low blood sugar figure usually causes no serious inconvenience so long as the patient's defective metabolism is not subjected to any extraordinary strain, but severe physical or mental exertion rapidly causes collapse, while ketosis, sickness, and other symptoms due to an insufficient supply of available carbohydrate develop from causes which would have little or no effect upon a normal individual.

TREATMENT.

The treatment employed in this series of cases has been the same in principle as I have described in previous papers.[4] Increasing experience of chronic hypoglycaemia has emphasized the etiological importance of acquired infections and intestinal disorders; and as greater attention has been paid to their detection, and more efficient measures for dealing with them have been adopted, there has been a corresponding improvement in the results. Where dietetic treatment alone has been possible owing to the absence of any discoverable cause, the immediate effects have been satisfactory, but, since it has usually been found that a recurrence of the symptoms followed when the treatment was discontinued, it is evident that an artificial increase in the blood sugar brought about by feeding with glucose, or a diet rich in carbohydrate, has only a palliative effect, as our experience with hypoglycaemic mice has also demonstrated. Observations on these animals have shown that they do not interbreed readily, but that they can be induced to do so by mixing a daily dose of glucose with their food. At first all the progeny were either born dead or only survived a few days; then, as the glucose feeding was continued, some lived for a week or two, later, the death rate diminished, and successive families lived for progressively longer periods, until eventually the mortality was no greater than in the families of normal mice. No matter how long the parental feeding with glucose was continued, however, all the offspring had a low blood sugar and were sterile, and when the administration of glucose to the parents was discontinued they ceased to produce living families. These experiments also demonstrated that, although glucose feeding did not eliminate the cause or influence the transmission of the hereditary defects from which the parents suffered, it prevented the premature death of the offspring and increased their expectation of life. Clinical experience and other experiments with animals have likewise shown that early prophylactic treatment of the descendants of hypoglycaemic parents prevents the development of serious symptoms, and has a beneficial effect on their general health.

There is still much to be learnt about all abnormalities of carbohydrate metabolism, and particularly about those associated with an unusually low blood sugar level, but opportunities for investigation are by no means rare, as the number of cases I have met with in a comparatively short period indicates. I hope this paper may be the means of directing the attention of others to what is, I believe, a matter of considerable clinical importance.

FLAVINE IN PERINEAL DRESSINGS.*

BY

M. A. DOBBIN CRAWFORD, M.D., B.CH., M.A.O., F.R.C.S.I.,

HONORARY ASSISTANT SURGEON, LIVERPOOL AND SAMARITAN HOSPITALS FOR WOMEN, AND LIVERPOOL MATERNITY HOSPITAL.

THE success of plastic operations on the vagina depends largely on the nursing and after-care received by the patient. Though it is comparatively easy to adopt an adequate operative technique it is sometimes difficult to ensure the healing of the wound by first intention.

The circumstances which may interfere with healing are obvious. The suture line is never dry, being made wet by discharge from the cervix, by menstrual flow, by micturition, and by perspiration. The part is not only constantly wet, but it is bathed in organisms; cervical discharge is never sterile. The skin is always liable to contamination during defaecation, while the urine of many patients subjected to this operation is infected with the *Bacillus coli*. This last circumstance I have found most troublesome of all. The repeated wetting of the wound by infected urine (of which some drops always ascend to the vagina if the patient be recumbent) is, I believe, the most common cause of sepsis following vaginal operations. The infected discharges cause catgut to separate early and silkworm-gut to cut out. Taking these circumstances into consideration it would appear extraordinary that such a wound ever heals by first intention.

I have used a variety of treatments and dressings, pre-operative and post-operative, the common object being to disinfect the vagina before operation, and afterwards to cleanse the wound after each micturition by swabbing with a mild antiseptic and then to apply a dry dressing. I have tried mercury biniodide, eusol, milton, saline, picric acid, iodine, and flavine in water, and I have come to the conclusion that to wash a clean wound with a watery solution of any antiseptic is bad surgery, and that a perineal wound must above all else be protected from urine.

In one of the hospitals to which I am attached patients who have had vaginal operations are allowed to pass water twice only in twenty-four hours, and then in a kneeling position. The woman kneels over a small chamber, her forearms resting on a pillow laid across her thighs. It is difficult to persuade a private patient to adopt this procedure. I have even tried keeping the perineum dry by allowing micturition only through a small funnel held directly below the urethra, but with varying results. The straightforward cases did very well; others gave trouble, one or more stitches giving way too soon, and healing was completed by granulation, the result being more or less imperfect.

My troubles culminated in a case in which I had done a Fothergill's repair, and on the twelfth day I returned from a Sunday's excursion to find that the lady had had a severe secondary haemorrhage; the city had been searched for help, and after some delay a colleague had kindly come to the rescue and packed the vagina. The haemorrhage was due, of course, to sepsis. On removing the pack the bleeding recommenced, and, finding nothing to tie, both colporrhaphy wounds being laid bare in their upper parts and the raw surfaces oozing, I cast about in my mind for some antiseptic lubricant which would clean up the infection and would not dislodge clots in the vessels when withdrawn. I thought of an emulsion of flavine in paraffin, which I had seen used in prophylactic disinfection of the abdominal wall after laparotomies. I irrigated the vagina to get rid of the offensive clot, then packed with gauze soaked in the emulsion. I was amazed at the speed and completeness with which the sepsis cleared up and the wounds healed.

Since that time, two and a half years ago, I have used this emulsion of flavine in paraffin as a routine dressing in all perineorrhaphies, to my great comfort and success. I use it as a protective dressing. As a rule I wait for twenty-four or forty-eight hours, so as to allow the natural sealing of the wound by serum, then at latest on the third day, the day on which aperient is given and before the bowels are opened, I start dressing with a narrow strip of gauze about three inches long, soaked in the emulsion, applying it by means of a forceps laid upon the colpoperineorrhaphy wound. A little of the emulsion enters the vagina and protects the colporrhaphy wounds higher up. The dressing is renewed after each micturition. The results have been most happy. When operating now for the cure of prolapse I know that with reasonable nursing the wound will heal by first intention, and that the ultimate result will approximate very nearly to the immediate result obtained when the patient leaves the table.

I have also used this emulsion to my satisfaction as a perineal dressing after craniotomy in cases where previous futile attempts to deliver by forceps had caused great bruising of the vulva. It is made up at a strength of 1 in 1,000, though probably in greater dilution it would be equally effective.

* Abstract of a paper read before the North of England Gynaecological and Obstetrical Society at Liverpool, October 25th, 1929.

FLAVINE IN GENERAL SURGERY.

BY

W. J. SHEEHAN, M.B., B.CH., B.A.O.,

MEDICAL OFFICER, NORTH RHODESIAN ADMINISTRATION.

THE three following cases illustrate the value of flavine as a bactericide and as an antiseptic in general surgery.

Traumatic Moist Gangrene of Arm.

On October 25th, 1929, a native woman, aged about 24 years, was brought by canoe to Mongu from Libonda, on the upper Zambesi River about three days away, suffering from moist gangrene of the right arm. The history of this case was that, about two months previously, the woman ran into her finger a piece of wood, which she removed with a needle. The hand swelled up and, as she described it, became rotten. When I saw her there was massive necrosis of the limb, extending up to the junction of the lower and middle thirds of the right arm, where a line of ulceration had formed, revealing necrosed bone. Above the area of ulceration the gangrenous process was extending through the tissues of the arm, which were oedematous and greenish-black in colour, from which very fetid yellow pus was oozing copiously. The skin on the inner side of the arm was involved right up to the axilla. The patient was greatly debilitated, and looked very toxic.

Amputation through the shoulder-joint was impracticable owing to the high involvement of the skin on the inner side of the arm, and the patient's condition would not have tolerated such a formidable procedure as an interscapulo-thoracic amputation. I did a guillotine amputation of the arm a handbreadth below the joint, cutting through living tissue as much as possible, ligated the vessels, and treated the stump as an open wound, using flavine (1 in 1,000) dressings only. The result was dramatic, the foul sloughing tissue becoming bright red, and clean within four or five days. The patient is making an excellent recovery, the temperature since the operation having been absolutely normal.

Traumatic Moist Gangrene of Leg.

On May 17th, 1928, a male native, aged about 35 years, was brought to Mongu for treatment, suffering from spreading moist gangrene of the right leg and thigh. The history of the case was that three months previously, when proceeding to seek work, the patient developed a small sore on the dorsum of the right foot, on the Lui River, three or four days from Mongu; he could not say if the sore was due to an injury or not. The foot became swollen, rotted, and dropped off at the ankle-joint; the disease spread up the leg, which fell off at the knee-joint.

When I saw him about 3 or 4 inches of the lower end of the femur were protruding; the bone was black and necrosed, and a necrosed patella was adherent to the muscles, which were a greenish-yellow pultaceous mass, from which a horribly offensive yellowish pus was freely exuding. The gangrenous process was

extending, and the skin of the thigh was very oedematous and undermined. Amputation through the hip-joint was suggested, but this he declined, and the case looked absolutely desperate. He was intensely toxic, in great pain, and his condition was so bad that I felt some other line of treatment should be adopted to relieve him. Morphine hypodermically was given nightly, and the limb was dressed twice daily with flavine (1 in 1,000). As in the previous case recorded, the result was highly dramatic. Within three or four days the gangrenous process had ceased, the greenish-yellow tissue became a bright red granulating surface, and the necrosed end of the femur and the patella dropped off. He made a complete recovery, and left the hospital with what looked like a neat conical amputation stump.

Traumatic Hernia of the Spleen.

On October 24th, 1929, a native woman, aged about 25 years, was brought to me for treatment. The history was that on the previous day, near Kalabo Station, she had been stabbed in the abdomen with an assegai. Examination revealed a big portion of the spleen protruding through a wound in the left hypochondrium. The protruding organ was strangulated and dusky in colour.

The operation of choice would probably have been complete splenectomy, but as the woman had been already carried in a canoe for twenty-four hours, and assistance was very inadequate—a nurse and a native orderly—I decided to remove only the damaged part of the organ.

The abdomen was opened under general anaesthesia, the strangulated portion of spleen was ligated and excised, a drain was inserted, and the abdominal wound closed and dressed with flavine (1 in 1,000). There was a slight temperature and some distension for two or three days, with a purulent discharge from the upper edge of the wound, which seemed to come from a localized abscess. Apart from this, progress was uneventful, and the woman is nearly ready for discharge from hospital. To complicate matters, respiration failed in the middle of the operation, and artificial respiration had to be employed, with consequent protrusion of intestine, which did not make things any easier.

I thought that this case, owing to the rarity of the condition, might be of some interest. Lejars says that Vanverts has collected 29 cases, of which only 6 have occurred during the last twenty-five years.

I am indebted to Dr. P. H. Ward, P.M.O., Northern Rhodesia, for permission to publish this paper.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CURE OF THROMBOPENIC PURPURA BY LIVER.

THE patient (aged 23) whose case is recorded below gave a history that ten years ago, after an operation for tonsils and adenoids, he bled very profusely, and was thought to be a bleeder. He also stated that there were blood blisters inside the mouth on January 31st, 1929, that there was then a little bleeding inside the mouth, but that this improved, and then, on February 20th, became worse. Previous treatment had been by injections of collosol calcium and of haemoplastin.

He was examined on March 2nd, 1929. Blood was oozing from the margin of the gums in both the upper and lower jaws, and there were numerous petechiae on the mucous membrane of the mouth, and in the skin around about the shoulder girdles, and a small number of petechiae elsewhere. The urine contained a small amount of urobilin, no albumin, no blood, and no sugar.

A blood count (by Dr. Clarke) showed: red blood corpuscles 4,940,000 per c.mm.; white corpuscles 12,500; haemoglobin 86 per cent.; colour index 0.87. *Differential count*: polymorphonuclears 80 per cent., lymphocytes 12.5 per cent., large mononuclears and transitionals 1.5 per cent., cosinophils 6 per cent. The red cells were apparently normal; platelets practically absent. Bleeding time and blood coagulation time were not tested, but the films showed almost complete absence of platelets.

He was put on treatment by liver as for pernicious anaemia, and also given liquor arsenicalis. On March 6th the bleeding began to diminish, and by March 11th it had ceased entirely.

Examination on June 28th showed that platelets were present in normal numbers. His liver was reduced to half the amount.

At the present time he seems fit and well, and does regular work on his father's farm. He has slight and occasional bleeding from his gums, but no blood blisters. He takes a cooked liver meal once or twice a week.

HERPES OPHTHALMICUS COINCIDENT WITH VARICELLA IN ADULTS.

IT is now a well-established fact that herpes zoster may be followed in eight to twenty days by an outbreak of chicken-pox in contacts who have not previously suffered from varicella. Bokay in 1892 reported nine cases of this type, where the possibility of infection from other sources could be excluded. Parkes Weber has described a series of cases, and Le Feuvre made an analysis of fifty cases illustrating the singular connexion between the two diseases. Ker reported that in eighteen months three out of seven appearances of herpes zoster in his wards had been followed by chicken-pox, otherwise quite unexplained.

The cases here described were admitted to St. Mary, Islington, Infirmary, Highgate, within a short time of one another. They are interesting in that both eruptions were present at the same time, the varicella eruption becoming manifest six days after the first signs of the herpes; moreover, chicken-pox is unusual in adults, and one of our patients was over 80 years old.

Case 1.—A man, aged 69, noticed on December 6th, 1929, a small pimple over his left eye, which gradually became worse. He was admitted on January 11th with well-marked herpes ophthalmicus on the left side, the rest of the skin being quite clear. The next day an eruption, having the typical appearance and distribution of varicella, appeared. Recovery was uneventful, except that there was scarring from both the herpes and the varicella to an unusual extent. There were no further cases, as the patient was isolated from the beginning.

Case 2.—A man, aged 80, had on December 19th, 1929, what he described as a cold in his head with irritation of his left eye. He did not feel very well, and attended a general hospital on December 26th, from which he was sent on to us. On admission, seven days after the onset of the disease, he had a well-marked herpes ophthalmicus on the left side, with a rash that was typical of varicella in appearance and distribution. He was isolated with the previously mentioned case, and had an uneventful recovery.

In neither case had the patient suffered from a previous attack of chicken-pox, and the question of a recent exposure was investigated and proved negative. There was no possibility of the eruption being due to drugs, as the patients had had no treatment prior to admission.

We wish to thank Dr. W. R. M. Turtle, medical superintendent, for permission to publish these cases.

TORSION OF THE GALL-BLADDER.

THE following case of torsion of the gall-bladder is of some interest, and is reported on account of its comparative rarity. One case is cited in Rose and Carless's *Manual of Surgery*, but no other is described in any of the several textbooks consulted.

The patient was a married woman, 77 years of age.

Previous History.—The left breast had been removed for carcinoma four years previously; apart from this she had been in good health until the onset of the symptoms, which was sudden, with severe pain in the right side of the abdomen just below the costal margin, and increasing in intensity. Five minutes after the pain commenced there was a feeling of nausea, followed by vomiting, first of undigested food, and later of bile. There were as many as ten such attacks of vomiting, but no jaundice was present.

Condition on Examination.—The temperature was 98° F. and the pulse 84, regular, and of fair tension and volume. The respirations were 20. The abdomen was protuberant, and there was fullness in the upper part of the right hypochondrium. In this region there was a very tender, painful pyriform swelling, which extended for 3 inches below the costal margin; it was 2 inches in width, and moved on respiration. A diagnosis of acute cholecystitis was made.

Operation.—An upper right-sided paramedial exposure was performed, when a very enlarged dark plum-coloured gall-bladder revealed itself with a definite mesentery 1½ inches long by 1¼ inch broad; the organ was twisted about its base in a clockwise direction through 180 degrees. Cholecystectomy was performed, and the gall-bladder was found to contain one large stone. Convalescence was uneventful.

I have to thank Mr. C. H. Larer for permission to publish this case.

East Surrey Hospital, Redhill.

SUDDEN DEATH FROM INJURY TO THE CEREBRAL PEDUNCLES.

THE following very unusual case of sudden death from trauma seems worthy of record.

A middle-aged, healthy, well-built man was riding his bicycle in a gale. A sudden gust of wind caused him to lose control of his cycle and he fell off, striking his head against the pavement. He was picked up dead, and taken to Addenbrooke's Hospital, Cambridge.

Post-mortem examination revealed a fissured fracture of the anterior fossa of the skull of minor degree, and, in addition, the cerebral peduncles had been cut almost clean through, presumably by impact against the dorsum sellae. No other abnormalities were found.

I am indebted to Dr. J. F. Gaskell for permission to record this case.

Reports of Societies.

THE CURATIVE ACTION OF DIGITALIS IN TOXAEMIA.

AT a meeting of the Section of Medicine of the Royal Society of Medicine, on April 25th, presided over by Dr. R. A. YOUNG, a communication was made by Professor W. E. DIXON and Dr. G. N. MYERS on the curative action of digitalis in toxaemia.

Professor DIXON explained that the large-scale animal experiment which was recorded in the paper arose out of an attempt to determine whether digitalis was or was not of any value in pneumonia. Clinicians were divided on the point, some stating that the use of digitalis rendered the patient more liable to die, and others that it increased the probability of cure. On the experimental side there was exactly the same division of opinion, about half the research workers stating that as a result of their observations digitalis had been shown to be of value in pneumonic and infective conditions, and the other half that it had no value whatever. A suggested explanation of the difference was that investigators had been so engrossed in studying the action of digitalis on the heart that no other action had been recognized or expected. It was impossible to give animals pneumonia and to ensure their death in the absence of exceptional measures, and therefore in these experiments, which were with guinea-pigs and rabbits, resort was made to the use of a toxin, nearly all the mortality in pneumonia being attributable to toxaemia. The diphtheria toxin was chosen for the purpose of the experiment, because the minimal lethal dose was so definite. The experiments showed consistently that if a reliable tincture of digitalis were given the animals survived subsequent injections of bacterial toxin, even if the amount of toxin was three times the minimal lethal dose, while the control animals, which had had the toxin without the previous digitalis, invariably died. The same effect was obtained when the toxin was injected first, provided that the injection of the digitalis was not too long delayed. It was also found that the glucosides from digitalis and strophanthin (from *S. kombé*) exerted some life-saving effect, though not to the same extent as that given by digitalis, while *g*-strophanthin, or ouabain, which was official in the *United States Pharmacopoeia*, and was used for the standardization of tincture of digitalis, had no action of this type. This last substance was an ideal control, because it was absolutely valueless. It acted on the heart like digitalis, but had none of its life-saving properties. Animals which received ouabain died even a little more readily than those which had received the toxin alone. Strophanthin, if given for a sufficiently long time, acted nearly as well as digitalis, the treated animals surviving and the controls dying. The effect of toxin on the animals which had received digitalis was different from that on normal animals, in that while the former responded by a decided leucocytosis, in the latter the leucocytosis was never a decided feature, and might be absent. Experimental and clinical evidence showed that toxins generally killed by causing circulatory failure associated with enormous dilatation of the splanchnic vessels and a progressive fall in blood pressure, a condition which was not due to the depletion of the suprarenal glands.

In brief, the result of the experiments was to show that if digitalis was given to the animals first, large quantities of toxin could be given, and the animals would survive, and that, even if the toxin were given first and the digitalis injected not too long afterwards, animals which ordinarily would have died under the dose of toxin could almost certainly be kept alive. How did the digitalis act? It appeared that it was of benefit in these shock conditions because it was retained by the tissues of the vascular system. It seemed as though, when an animal was under digitalis, there was little or no place for the absorption of toxin. Digitalis had to be administered for many days before perfect action was obtained, and this fact suggested that the drug occupied some portion of the cardiac structure to which the toxin normally attached itself; at all events, if digitalis were first given, and had time to act, the toxin was without effect, but if the toxin were injected first, subsequent digitalization, if delayed, might be too late to be effective. If this suggestion was valid, then the life-saving properties of digitalis in toxaemia were not explained by the known beneficent effects of the substance in cardiac disease, so well exemplified in auricular fibrillation and mitral regurgitation.

The subsequent discussion took the form of questions addressed to the authors. Dr. PARKES WEBER asked how the doses employed in the experiment corresponded with what would be necessary in the human adult, and remarked that when digitalis was recommended seriously for pneumonia it was recommended in very large doses. Professor DIXON said that he could not answer this definite question, but the more digitalis that could be introduced into the vascular system the better. Dr. KINGSTON BARTON asked whether it was possible to make use of digitalis as a preventive, on the analogy of building up the resistance to infection by means of substances containing vitamin A. Professor DIXON replied that, as in the case of vitamin A, unless there was a deficiency of a given constituent, no advantage was to be gained by taking more. Dr. NORMAN MYERS, in reply to a question as to whether electrocardiographic observations made on these animals showed an inversion of the T wave, said that with guinea-pigs there must be heavy digitalization to secure a change in the T wave; the digitalis in these experiments had to be given in slow progressive fashion, otherwise the toxic effects of the drug would appear. Large amounts of digitalis were required to produce inversion of the T wave, and in these experiments the phenomenon was not recorded.

Dr. R. A. YOUNG, from the chair, said that this communication was encouraging because it led one to believe that drugs and other such means might have an effect upon the toxins of bacterial bodies. It had become customary to imagine that the only chance of influencing toxins was by antitoxins. Some balneologists, however, had recently claimed that their waters exerted an antitoxic or at any rate a detoxicating effect in certain bacterial infections, and the present work suggested further lines of inquiry. It was also interesting to find pharmacologists confirming and extending belief in drugs; so often their work had tended to shatter beliefs previously held.

Ganglionectomy in Chronic Arthritis.

At the same meeting Dr. L. G. ROWNTREE, chief of the division of medicine, Mayo Clinic, gave a cinematograph demonstration of the value of ganglionectomy in certain cases of chronic arthritis. The cases selected were those of arthritis deformans, but without marked osseous change, and the sympathetic ganglions which controlled the calibre of the blood vessels were removed. In some instances the second, third, and fourth lumbar sympathetic ganglions were excised, in others the last cervical and the first two dorsal. Only 18 cases had been so treated out of many hundreds which came to the clinic, and the speaker was careful to point out that the treatment was not a panacea. Patients with cold and clammy hands and feet and with marked sweating were preferred. The best results were obtained in the hands, feet, ankles, and wrists; good

results in the knees and elbows; and less marked improvement in the shoulders and hips. In properly selected cases the treatment was followed by excellent results. Dr. Rowntree showed two reels of cinematograph film illustrating the patients before the operation was performed and the gradual recovery of function of the joints: conspicuous sequels were the disappearance of the pain, swelling, and deformity, the return of function to the joint, and the increase of muscle tone. The operation presented no difficulty after the field had been exposed; the ganglia were as apparent as stripes in clothing, and could be removed *en bloc* without difficulty. The operation for the upper extremity was not at first undertaken, as there was some uncertainty as to what exposed should be done. Then a posterior approach was attempted through the ribs, exposing the last cervical and the first and second dorsal, and the result was quite successful. In the operations for the lower extremity, using the abdominal method of approach, there had been some disturbance of intestinal function in two cases. The operation was of considerable magnitude and should be attempted only by a neurological surgeon. The first of this series of eighteen cases now dated back for four years; in the others the operation had been performed during the last year. The improvement in walking and the use of the feet and hands was well indicated in the films.

INDICATIONS FOR ELECTROTHERAPY.

AT a meeting of the Manchester Medical Society, on April 2nd, at Manchester University, with the president, Professor ALBERT RAMSBOTTOM, in the chair, Dr. R. SHAFFER read a paper entitled "Some aspects of electrotherapy," his object being to direct attention to some less well-known conditions in which this treatment was valuable.

Dr. Shaffer said that the cases considered had been treated in the electrical department of the Manchester Royal Infirmary. The first group consisted of 65 patients with lacerations, septic wounds, and cellulitis, who had been treated with zinc ionization. A case of osteomyelitis of the tibia which had been discharging for nine months had healed after two months' other treatment still had a raw which after twelve months' ionization. A burn in the leg area of 1½ in. diameter healed in three months under ionization. The speaker remarked that the sequels of cellulitis and whitlows usually caused much disability, owing to the matting together of tendons and joints in the resulting scar tissue. The treatment of these conditions was a triumph of electrotherapy, and consisted of diathermy, chlorine ionization, massage, and movements. many joints had thus been rendered useful which would otherwise have been greatly impaired as regards earning power. In 27 cases treated thus to loosen scar tissue there had only been one failure. A burned wrist took eighteen months to heal, and, naturally, was stiff and useless owing to the resulting scar tissue; three months of ionization treatment produced an efficient joint. Insurance societies would be saved large sums in compensation if physiotherapy were utilized for such injuries and their sequels, since the permanent disability would be greatly diminished. Similarly, much pain and incapacity would be prevented by the correct treatment of injuries in the region of joints other than those of bone. The persistence of pain and stiffness which caused such disablement was due to adhesions in and around the joint. By means of diathermy, radiant heat, massage, and early movements the patient would be saved much time and trouble, and the earlier such treatment commenced the better. There were 36 patients with chronic pain and stiffness after trauma, which had existed for an average of some months; most of them were discharged fit for work in about two months. An interesting use of faradism was the treatment of the early stages of flat-foot. A series of graduated contractions served to exercise the small muscles of the foot without strain, and, as they became more developed, they took more of the load, thus resting the over-stretched ligaments. If the joints were stiffened the foot required preliminary treatment with diathermy and manipulations. There were 25 cases of this kind, and the average treatment for 22 lasted ten weeks; the remainder persisted for five to six months before they were fit for discharge.

Diathermy was a method utilizing an alternating current of very high frequency, made to oscillate between two plates. Because of its frequency, 600,000 per second upwards, the nerve endings were not stimulated and chemical changes did not occur. The sole effect was the production of heat, which thus occurred in the tissues. The beneficial effect of diathermy was due to this deep heat. In treating any form of visceral congestion, diathermy was a logical procedure, since the deep heat produced would cause an increase in the effluent blood; this was obviously superior to any form of hot external applications. On this principle Dr. Eaton Stewart of Boston had been treating cases of lobar pneumonia with diathermy, and had reported striking successes. The total number of cases recorded in his book was 254; of these 219 patients recovered and 35 died, representing a mortality of 13.8 per cent. The following points of importance were noticed in this series, which included cases from six different seasonal epidemics and all the types of pneumonia. In 95 per cent. of these cases the temperature began to drop by lysis. Of those in which treatment commenced before the third day only two patients died, one being an old diabetic with pulmonary abscess. There was no constant change in the number of respirations, but their character was markedly improved and pain was diminished. A few hours' sleep usually followed each treatment. The cyanosis was constantly and markedly improved in every patient treated. Dr. Walsh of Tennessee had also reported a number of patients, 95 being treated with diathermy with a mortality of 12.4 per cent., and 59 being used as controls with a mortality of 20.3 per cent.; 122 were negroes and 32 whites. Dr. Shaffer went on to suggest that the use of diathermy in pneumonia, depending as it did on physiological principles, was worthy of investigation in this country. His own experience of this method in chest diseases was as yet limited to a few cases of chronic bronchitis, but the relief obtained was most gratifying.

Empyema complicated by Pneumothorax.

Dr. G. JESSEL read a paper on a case of empyema with perforation of the bronchus and partial pneumothorax. Having briefly referred to cases of spontaneous pneumothorax due to bronchiectasis and pulmonary tuberculosis that he had recently met with in his own practice, he described a case occurring in a patient with empyema. Perforation of a bronchus was briefly mentioned in most textbooks as a complication of empyema, but few details had apparently been recorded.

A youth, aged 17, with a history of previous good health, was suddenly taken ill in February, 1929, with what appeared to be influenza. Pneumonia was subsequently diagnosed, and after several weeks his doctor referred him to the local tuberculosis officer. He was admitted on August 7th, 1929 to the Peel Hall Pulmonary Hospital for investigation; his weight was then 6 st. 2 lb., the evening temperature 99°, and the pulse 102. The expectoration was profuse. The right lung was dull on percussion and the breath sounds weak, with many crepitations in front; tactile vocal fremitus was present, but no splash or coin sound was heard. Microscopical examination of the sputum showed cocci arranged in chains, but no tubercle bacilli. Dr. Davey of the Public Health Laboratory, Manchester, inoculated two animals and identified the organisms as haemolytic streptococci. A skiagram showed a dense homogeneous opaque shadow with the upper margin horizontal at the level of the fourth rib in front, merging with the cardiac and diaphragm shadows. Above and to the outer side was a clear pocket bounded externally by the chest wall, and with its inner margin concave outwards midway between the chest wall and mediastinum. Above and to the inner side of the clear area was a shadow of moderate and uneven density extending to the apex of the lung. The heart was not apparently displaced. The sputum gradually diminished in amount, and the general condition improved. On September 5th he complained of headache and pain in the right side of the chest. Next day his temperature rose to 100.6° and he coughed up half a pint of thick pus. His temperature then became normal and he felt better. The physical signs at this time were defective movement of the right side of the chest, tactile fremitus present all over; percussion dull especially at the base, with weak breath sounds and a few crepitations over the lower lobe, but no breath sounds audible over the lower lobe. He was discharged from hospital on September 25th much improved.

but subsequently he had a relapse and died. Although the pus found an outlet through a perforation of a bronchus, this proved to be insufficient, and the speaker thought it was arguable that resection of ribs should be performed in these cases as in ordinary cases of empyema.

A Form of Progressive Muscular Atrophy.

Dr. W. J. S. REID described a series of five cases, which he had seen during the past ten years, of progressive muscular atrophy of the atonic atrophic type, in which syphilis seemed to be the only etiological factor. The condition began in the small muscles of the hand, spreading to the extensors of the wrist and then to the shoulder girdle. No sensory changes were discovered at any time and no other signs of neurosyphilis. One patient had shown signs of bulbar paralysis, which was very unusual. The pathology was discussed, the speaker's opinion being that the cases were meningo-myelitic in origin. All had positive Wassermann reactions in the cerebro-spinal fluid, but Dr. Reid believed the essential point in diagnosis was an increase of the cell count. Treatment was successful in every case in arresting the condition. The speaker commended the intravenous injection of silver salvarsan, followed at once by lumbar puncture and the withdrawal of as much fluid as possible. The good effect of this procedure might, he added, be due to an increased entry into the cerebro-spinal system of the arsenical remedies, but, possibly, to the puncture alone. The condition was a subacute inflammatory condition, and therefore lumbar puncture alone might be expected to lead to improvement. Emphasis was laid on the occurrence of these cases which clinically revealed a picture akin to that of lead palsy; every care should be taken to exclude syphilis. When this infection was the cause the progress of the condition could be arrested in practically all cases.

CHORDOTOMY FOR PAIN.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on April 4th, with the president, Mr. R. ATKINSON STONEY, in the chair, Mr. A. A. MCCONNELL read a paper on *chordotomy for pain*.

Mr. A. A. McConnell described four cases in which the antero-lateral tract of the spinal cord was divided for intractable pain. One patient had post-herpetic neuralgia of the tenth thoracic nerve, and another had arthritis of the hip; the third suffered from cancer of the bladder, and the remaining one from sarcoma of the pelvis. In each case the pain was abolished, but the cancer patient died twelve hours after the operation; her general condition was bad, owing to prolonged pain and sepsis. Mr. McConnell concluded that this operation should be considered in all cases of intractable pain below the shoulder girdle, and should be performed at an earlier stage than was usual at present.

Dr. F. C. PURSER, referring to one of Mr. McConnell's patients whom he had seen, said that this patient had been much racked with pain, and was not a very good subject on whom to test sensation. The sense of pressure pain was not lost, but greatly diminished. The sense of vibration was also tested, and at the tenth rib the patient appreciated vibration perfectly well on both sides. At the iliac crest there was no sensation at all on the right side. Below the iliac crest vibration was occasionally felt, if it was extremely strong, on the left side, but was not felt at all on the right. The PRESIDENT mentioned that he had assisted Mr. McConnell at his first operation in 1925. There was a certain amount of difficulty in defining the exact position of the cord, but with experience and practice he felt that this would disappear. Mr. McConnell's results were extremely satisfactory, in spite of the fact that some of the cases had been left too long before the operation to gain as much advantage as they might have done had it been performed earlier. Mr. H. STOKES thought that in some cases loss of the sense of pain might be a disability.

Mr. MCCONNELL, in reply, said the operation was usually simple, but not always; it could be made more simple by opening the arachnoid separately from the dura. He agreed that loss of pain might be a disability in some cases. In the limbs the patient lost pain, but did not lose the sense of touch, and this was, to some extent, a protection. He would not operate in any case in which there was any prospect of relief by other means.

Clinical Cases.

Dr. R. R. WOODS showed a girl, aged 17, with an obscure condition of the tongue, which had been present as long as she could remember. The tongue was a good deal larger than normal; its edges were stripped of papillae, and a series of deep fissures ran radially from the centre to the edges, best seen when the tongue was pointed downwards. The whole appearance was as if the edges of the tongue had been combed with a sharp comb with teeth set far apart. There were indentations for the teeth round the edges, which were inclined to protrude between the teeth when the mouth was shut. The Wassermann reaction was faintly positive. After a provocative dose of novarseno-benzol (which was followed by a rigor) the Wassermann reaction was plus 2. Dr. Woods asked: Was the condition pathological or was it a congenital abnormality? If pathological, what was the condition? Had it any connexion with the Wassermann reaction? Was the Wassermann reaction absolutely reliable in such a case? The PRESIDENT said he did not consider the tongue to be of a syphilitic type; the slight development of fringes on the under part caused him to think that the condition was congenital. Mr. F. GILL reported that he had recently seen a similar case in a man, aged 22, in which the condition was more marked. He had heard of another case in a girl, and thought the condition was a congenital abnormality.

Dr. T. G. WILSON exhibited a specimen of hairy or dermoid polypus of the nasopharynx, removed from an infant aged 6 months; the growth was about the size of a marble, reddish in colour, and of an elastic consistency. It had been causing increasing respiratory obstruction since the child was a month old. Dr. Wilson also showed another similar growth which he had exhibited at the Section of Pathology six weeks previously. This second hairy polypus had produced intermittent attacks of asphyxia by acting as an imperfect ball-valve at the entrance to the larynx. It had been removed when the infant was some twelve hours old. In both cases recovery was uneventful. Dr. Wilson emphasized the rarity of the condition, and stated that these were the first two cases to be described in Ireland. The PRESIDENT, referring to the name "hairy polypus," said that the growth appeared to be bald, but he supposed there were follicles in the wall; he suggested that these polypi might develop hairs if they were allowed to persist into adult life.

Mr. H. F. MACAULEY demonstrated a boy, aged 6, from whom he had removed a large ganglioneuroma of the left superior cervical ganglion, which appeared as an indefinite swelling of the upper third of the neck, with a large arterial trunk overlying it and pulsating forcibly directly under the skin. Convalescence was uneventful, except for the fact that it was accompanied by the presence of Horner's syndrome, due to the removal of the portion of the cervical sympathetic trunk involved in the growth. Mr. MacAuley reviewed the literature of the ten other cases described. The PRESIDENT said that this was an extremely rare case. It was curious that the tumour was so difficult to palpate in spite of its large size, but he supposed that the difficulty was due to its deep situation and the comparatively soft tissue of which it was composed. Dr. W. D. O'KELLY remarked that he had seen four such cases, but pathological information on the subject was limited owing to the rarity of the condition. Mr. A. A. MCCONNELL referred to a somewhat similar case which he had seen some years ago in a boy, aged 5, who had a lump at the base of his neck, just above the clavicle. There were no symptoms referable to the sympathetic, but at the operation a lump was found intimately connected with that structure. During removal the sympathetic was divided above and below, and a typical Horner's syndrome developed. The tumour proved to be a fibroma, and no nerve cells were found in it. Mr. McConnell thought, however, that clinically it was a true ganglioneuroma. Mr. MACAULEY, replying, said that he had traced 51 cases of this condition, but they were apparently scattered, no one observer having seen more than two cases.

Reviews.

HUMAN PHYSIOLOGY.

ERNEST STARLING died in 1927. The loss to physiology was great; but he left us a record of brilliant experiment and of constructive thought. He left also his *Principles of Human Physiology*.[1] It is difficult for a reviewer of the present generation to contemplate the book without thought of the man. His personality was amazing. It was manifested in his research work as in all his human relations. It was manifested also in his teaching, in his lectures both to specialists and to medical students, and it penetrated, even, the almost impersonal barriers of a student textbook. He felt the obligation of a teacher to convey to his students the faith—not merely the works of the faith. His students remembered him, and the memory gave assurance that the study of physiology had been of service to them though they should never again consciously apply its principles or practise its arts. Not to many is this power given in wide degree. The student passes on; the teacher is forgotten; by so much is the power of knowledge dissipated. Starling completed the power edition of his book only a little while before his death. Already the demands of the press and the progress of knowledge have had to be met by a new and extensively revised edition. Authorship has passed to Professor LOVATT EVANS. We may rejoice in this succession, not only because it was the express wish of Professor Starling, not only because it continues the association of the book with University College, London, but also because of its assurance of continued authority. Starling left us a model of the classical textbook. The present author has preserved it and even more fully established it as a work of incomparable qualities. A detailed review of the text would be out of place, were it possible. The book is, however, too well known to require other than formal introduction. The present edition has been most extensively revised, and this is as it should be. When authorship passes on, there arises the opportunity for a more drastic revaluation to the times of the written word than, by the nature of things, a writer can bring to his own original work. An independent point of view demands some readjustment in the perspective of the old. Professor Lovatt Evans has accomplished his difficult task with complete success. Every chapter bears some sign of having been weighed judicially and remodelled to the better proportion of the whole. Elimination of matter now redundant, insertion of new material whose importance has grown in recent years, reorientation of argument for the better progress of the story, have all contributed to a book which will have few competitors. The qualities of authority, understanding, and vitality combine to preserve *Starling's Principles* as a completely satisfying work.

French physiologists are now embarked upon an ambitious enterprise. Under the general direction of Professor G. H. ROGER and the editorship of Professor LEON BINET an exhaustive Treatise on Physiology is in course of publication. It is intended that, within the next two years, the work should be completed in a library of eleven separate volumes. Already five of these—each of them a considerable volume exceeding 500 pages—have made their appearance, so that the project may be said to be well launched. In a general preface, Professor Roger defines those principles of physiology and those movements of recent thought which, in his opinion, should determine the scope, form, and proportions of a treatise of the dimensions projected. He emphasizes, in the first place, the close liaison which has always been and must always be maintained between physiology and practical medicine. For that reason the study of functional disorder will form an integral part of the work, justifying the full title of "Physiology: Normal and Pathological." For the rest Professor Roger accepts "function" as the foundation for the classification of physiological observation and deduction, outlines the levy which the subject makes upon other experimental sciences, emphasizing, in particular, the contribution of chemistry and physical chemistry, and claims the right to appropriate experimental psychology as a branch of physiology. Until the complete treatise is available it will not be possible to assay the measure of success which has attended the pursuit of these principles. It may, however, be said that the names of the thirty or so contributors to the treatise give ample assurance that the work will be fully representative of French, and, to a less extent, of Belgian schools of physiology. The five volumes already issued cover the subjects blood, lymph, and immunity; the internal secretions; muscle and animal heat; reproduction and growth; and the hepatic function and excretion. There remain—in press or in preparation—volumes upon general physiology; digestion; respiration; circulation; and (two) the nervous system. Of those published, only volume viii is before us: it is entitled "Muscle Physiology: Animal Heat."[2] Professor Lapicque is responsible for the general physiology of muscle, and succeeds in presenting a clear though highly detailed story. A rather elaborate chapter on chronaxie is added by Professor Bourguignon, while interesting discussions of fatigue and of locomotion are contributed by Professor Chailley-Bert. The problem of animal heat is surveyed in a comprehensive manner by Professor Lefevre, and the discussion is extended to the questions of fever and of temperature control by Professor Gautrelet and by Professor Binet. This part of the book is prefaced by an admirable summary of the physical laws of heat, mechanics, and energetics from the pen of Professor Weiss. Brief sections on bone by Professors Leriche and Policard, and on bio-electricity and bio-luminescence by Professor Strahl complete a volume which extends to more than 700 pages. The names of the authors cited above make an impressive catalogue of authority. A perusal of the weighty but generally entertaining text suggests that each contributor has engaged himself upon his task with care, discrimination, and vision. It is not possible to make any estimate of the relation of volume viii to the rest of the treatise. The fact, however, that within the volume itself there is little evidence of serious overlapping or incompatibility of treatment of related subjects by different authors gives promise that the work, as a whole, may be something more than a mere collection of monographs.

SICK CHILDREN.

THERE is room for a *Textbook on the Nursing and Diseases of Sick Children*,[3] written from an English standpoint, and the present work is well fitted to fill the gap. It has been produced by a small team of physicians and surgeons connected with the Hospital for Sick Children, Great Ormond Street, with the collaboration of the sister tutor at that institution, all writing under the able editorship of Dr. ALAN MONCRIEFF. The subject-matter of the book falls into two parts—a description of nursing methods as applied to children, and an account of the commoner diseases and disorders of early life, written specially to meet the needs of nurses and welfare workers. The teaching on both aspects of the subject is clear, detailed, and accurate, and is illustrated where necessary by some useful diagrams and photographs. The sections on nursing, indeed, could be read with advantage, not only by nurses, but by doctors. On the other hand, the utility of the chapters describing the medical and surgical diseases of children is less obvious. They are admirably written, and written with a reasonable degree of simplicity, but they seem to contain more information than a nurse, with her rather sketchy knowledge of anatomy and pathology, can appreciate. Is it really necessary (or advantageous), for instance, that a nurse should know the varieties of congenital malformation of the alimentary canal or the names of the myopathies—Hoffmann paralysis and the chief types of the myopathies? Will it make her a better nurse, or will it not rather make

her consider herself an amateur doctor? The authors, we suppose, would reply that the General Nursing Council, incredible though it may seem, does actually expect a nurse to possess this sort of information, for they give in an *appendix* the questions set at the State examinations for sick children's nurses during the last two years. We gather from these that a nurse may be asked what she knows of keloid, syndactyly, Hirschsprung's disease, dermoid cysts, and acetonaemia, or that she may have to give an account of the varieties of osteomyelitis with a description of their constitutional symptoms and local signs. So long as such questions are set it will be necessary for a candidate to get up enough information to enable her to deal with them, and certainly any nurse who has a fair knowledge of the contents of this book can face with equanimity even the examiners of the Nursing Council.

MEDICAL EXAMINATION FOR INSURANCE.

An author is unfortunate who, having something of importance to say, is unable to say it in good concise English. That Dr. PATERSON MACLAREN's book, *Medical Insurance Examination*,[1] meets a need is shown by the issue of a second edition. But his involved style is made even more irritating by his inveterate habit of splitting infinitives. Moreover, his desire for thoroughness has led him to introduce into his book masses of detail which must be known to every medical practitioner; and he takes credit to himself for trebling the space devoted in the previous edition to certain knotty problems in insurance work. Judicious use of the pruning knife would have shortened his 600 pages, and probably made them more readable. It is a pity, perhaps, that more use is not made by British offices of the mass of material that must be in their possession for the purpose of assessing lives. It has been left largely to American and Canadian companies to try to establish numerical ratings for almost every abnormal condition. At the same time, as Dr. MacLaren points out, striking a balance of the credit and debit points of the proposer is done *subconsciously* by every painstaking medical examiner. In the American system a vague summing up of impressions is replaced by a definite judgement on each impairment. If these vague impressions produce satisfactory results to all concerned, British proposers and examiners may well be thankful at being saved from the intricacies of the American medical report. From the scientific point of view it is another matter.

Among the conditions which arouse questionings in assessing lives at the present time are renal glycosuria; functional, or, as Dr. MacLaren prefers to call it, extra-renal albuminuria; rheumatic fever; pleurisy; high blood pressure; and over- or under-weight. About all these conditions it is by no means easy from Dr. MacLaren's book to discover what is the orthodox opinion, if any; but from the rating tables appended to each chapter it is possible to find out the importance attached to them by American and Canadian offices. In the section on hyperpiesis Dr. MacLaren calls attention to the great variations which may occur in the blood pressure at the functional crises of life, even in a quite healthy individual; so that in order to label a case of high blood pressure as "persistent" at least three readings should be taken on different days and at different hours. Where such procedure is practicable, he states that a systolic reading of 12 mm. Hg above the average for the age should be the maximal variation allowed without loading. Some latitude, however, appears to be allowed to persons who are 20 per cent. overweight. Their pressure may be 4 mm. over that of persons of average weight. A persistent systolic pressure above 155, with a persistent diastolic above 100, calls for an extra premium at any age. Many examiners, we believe, do not take so strict a view; but whether their lenity is based on ignorance of the American figures, or different English experience, we do not know. In discussing renal glycosuria, Dr. MacLaren quotes MacLean's view that persons with this condition should be accepted at normal rates, and McCrudden's statement that three patients had been observed over periods of nearly thirty years. From the ratings of the different companies it would appear that MacLean's view is by no means universally adopted. In loading for acute rheumatism the American offices seem to incline to leniency.

Apparently Dr. MacLaren's object is to plead for the universal adoption of some such method of rating lives as is used in America, whereby the amount of risk in various diseases and disabilities may be assessed, and met by various methods of loading. He is concerned because under present methods sheep of very diverse grades are herded into the same fold. He thinks that there is a great future for an insurance company which, taking only 100 per cent. lives, could quote rates far below the present scale. And in an appendix he supplies a draft "confidential report" and "personal statement" of such fullness as should frighten away any proposer, and cause the examiner to treble his fee.

MECHANO-THERAPY.

DR. MARY MULLINER in her book on *Mechano-Therapy*[2] does not profess to treat the subject in a comprehensive way. She writes in the preface: "The larger part of the author's practice, aside from hospital clinics, has been in corrective hygiene, with less of the distinctively orthopaedic work, hence the emphasis placed upon correct posture. . . ." This must be borne in mind, otherwise the reader will be surprised to find only scant reference to the treatment of fractures and injuries, while other branches of the subject are dealt with adequately.

In describing certain manipulations Dr. Mulliner advocates a technique which would not find general acceptance in this country. For example, if in effleurage the hand is moved "back and forth over the skin" as she advises, the movement would be devoid of the profoundly soothing effect obtained by Mennell and others in unidirectional—that is, centripetal—stroking. Again, to practise vibration of the arm for its stimulating effects on the patient would have far too exhausting an effect on the operator to justify its use. Vibration having a sedative effect of great value is described by Cyriax in *Elements of Kellgren's Manual Treatment*, and, properly performed, this treatment can be maintained without fatigue for long periods. The effect of rapid arm circumduction, Dr. Mulliner says, is to draw the arterial blood by "centrifugal force" away from the chest. This is a crude, mechanistic theory of the complex sequence of changes which occur in the circulation in blood and lymph vessels in a limb during passive rotation. It is comforting to find that the author stresses the fact that respiration is a normal reflex. Although this may seem obvious, it is often lost sight of by enthusiasts, who, by many and various breathing exercises, would tend to make respiration a voluntary process.

Briefly, this textbook is a helpful addition to existing works on the subject. Readers on this side of the Atlantic, however, will find the author's phraseology irritating. Here are two typical examples: "Knowledge of anatomy pays big dividends" (a point which some of our anatomical teachers might well question!); and on page 212: "The pains of neuralgia come and go. Those of neuritis never let up." Such expressions are all very well in a topical journal; they are out of place in a serious textbook.

AMERICAN MEDICAL WAR HISTORY.

AT the recent annual meeting of the Carnegie Trust for the Universities of Scotland, Lord Sands, who presided, described an American report, copies of which had been received by the Trust, as being shorter than the *Dictionary of National Biography* but larger than the Holy Scriptures. The same might be said of volume iii of the history of The *Medical Department of the United States Army in the World War*.[3] They do things thoroughly in the United States, and it is no surprise to find that this volume,
